Confirm placement of enteral feeding tubes. Determine feeding tube position in stomach by x-ray, confirm pH of 0 to 5 for the gastric fluid withdrawn through tube, or auscultate injected air before intermittent feedings. Observe for ability to speak and cough.	Malplacement of feeding tubes may result in aspiration of enteral formula. Clients at particular risk include those who are intubated, obtunded/comatose, and those who have had a neurological injury (e.g., stroke, MS, Guillain-Barré) or surgery of the head, neck, and upper GI system. Note: The reliability of the pH method is reduced if antacids or certain other medications have been given orally or via NG in the past 4 hours. In addition, when using auscultatory method to assess tube placement, air sounds can be transmitted to the epigastrium even if the tube is malpositioned in lung or proximal jejunum.
Maintain aspiration precautions during enteral feedings, such as the following:	
Keep head of bed elevated at 30 to 45 degrees during feeding and for at least 1 hour after feeding. Interrupt continuous feeding when client is in prone position for repositioning or transport.	Reduces risk of regurgitation or gastric reflux.
Inflate tracheostomy cuff during and for 1 hour after intermittent feeding.	Aspiration of enteral formulas is highly irritating to the lung parenchyma and may result in pneumonia and respiratory compromise.
Monitor gastric residual volumes (GRVs) between or before bolus feedings (as previously noted in ND: imbalanced Nutrition: less than body requirements) and high bolus feeding volumes.	Presence of large gastric residuals may potentiate an incompetent esophageal sphincter, leading to vomiting and aspiration. In addition, fast feeding rates with volumes exceeding 1500 mL/d are at higher risk of aspiration (Houston, 2017).
Note characteristics of sputum and tracheal aspirate. Investigate development of dyspnea, cough, tachypnea, and cyanosis. Auscultate breath sounds.	Presence of formula in tracheal secretions or signs and symptoms reflecting respiratory distress suggest aspiration.
Note indicators of NG tube intolerance, such as absence of gag reflex, high risk of aspiration, and frequent removal of NG feeding tubes.	May require consideration of surgically placed feeding tube, percutaneous endoscopic gastrostomy (PEG), or jejunostomy (J tube) for client safety and consistency of enteral formula delivery.
<b>Collaborative</b>	
Review abdominal x-ray if performed.	Confirmation of placement of gastric feeding tube should be obtained by x-ray.

### NURSING DIAGNOSIS: risk for imbalanced Fluid Volume

#### Possibly Evidenced By

Treatment regimen; [complications of nutrition therapy—high-glucose solutions, hyperglycemia; overhydration or dehydration]

Failure of regulatory mechanisms specific to underlying disease process or trauma

Inability to obtain or ingest fluids

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Fluid Balance NOC

Display moist skin, moist mucous membranes, stable vital signs, and adequate urinary output; be free of edema and excessive weight loss or inappropriate gain.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Fluid Management NIC</b>	
<b>Independent</b>	
Note presence of conditions (e.g., diabetes, intestinal obstruction, burns, sepsis, kidney or liver failure).	These underlying conditions associated with fluid imbalances may be present in the client receiving nutritional therapy. Both the conditions and nutritional therapies have fluid imbalance implications.
Note current treatment modalities (e.g., mechanical ventilation, surgery, major invasive procedures and devices).	These can cause/exacerbate fluid imbalances.
Assess for clinical signs of <b>dehydration</b> such as thirst, dry skin and mucous membranes, hypotension, or <b>fluid excess</b> , including peripheral edema, tachycardia, and adventitious breath sounds.	Early detection and intervention may prevent occurrence of excessive fluctuation in fluid balance. Note: Severely malnourished clients have an increased risk of developing <b>refeeding syndrome</b> (life-threatening fluid overload, intracellular electrolyte shifts, and cardiac strain occurring during initial 3 to 5 days of therapy). This potentially catastrophic complication can usually be prevented by starting feedings at low rates and advancing them slowly over several days (Mehler et al, 2010).
Incorporate knowledge of caloric density of enteral formulas into assessment of fluid balance.	Enteric solutions are usually concentrated and do not meet free water needs.
Provide additional free water via feeding tube or at bedside (if client can drink) and via feeding tube flushing tubing.	With higher calorie formula, additional water is needed to prevent dehydration or hyperglycemic complications.
Record intake and output (I&O), calculate 24-hour fluid balance, and measure urine-specific gravity.	Indicators of fluid balance. Specific gravity is an indicator of hydration and renal function.
Weigh daily, or as indicated; evaluate changes.	Provides for early detection and intervention as needed. Note: Rapid weight gain reflecting fluid retention can predispose or potentiate heart failure (HF) or pulmonary edema. Gain of more than 0.5 lb/d indicates fluid retention and not deposition of lean body mass.
<b>Collaborative</b>	
Monitor laboratory studies, such as the following:	
Serum potassium and phosphorus	Hypokalemia and phosphatemia can occur because of intracellular shifts during initial refeeding and may compromise cardiac function if not corrected.
Hematocrit (Hct)	Reflects hydration and circulating volume.
Serum albumin	Hypoalbuminemia and decreased colloidal osmotic pressure lead to third spacing of fluid and edema.
Serum transferrin	Reacts quickly to changes in protein status.
Prealbumin	Sensitive to low levels of protein.

**NURSING DIAGNOSIS:** **deficient Knowledge regarding condition, prognosis, treatment, self-care, and discharge needs**

**May Be Related To**

Insufficient information; insufficient knowledge of resources or interest in learning  
Alteration in cognitive functioning or memory  
[Information misinterpretation]

**Possibly Evidenced By**

Insufficient knowledge  
Inaccurate follow-through of instructions  
Development of preventable complications

<b>NURSING DIAGNOSIS:</b> <b>deficient Knowledge regarding condition, prognosis, treatment, self-care, and discharge needs</b> (continued)	
<b>Desired Outcomes/Evaluation Criteria—Client/Caregiver Will</b>	
<b>Knowledge: Disease Process NOC</b> Verbalize understanding of condition or the disease process and individual nutritional needs. Participate in learning process of treatment regimen. Be free of preventable complications.	
<b>Knowledge: Treatment Procedure NOC</b> Perform necessary procedures correctly, and explain reasons for the actions.	
ACTIONS/INTERVENTIONS	RATIONALE
<b>Enteral Tube Feeding/Total Parenteral Nutrition (TPN) Administration NIC</b>	
<i>Independent</i>	
Assess client's and significant other's (SO's) knowledge of nutritional state.	Determines content matter to be presented.
Review individual situation, signs and symptoms of malnutrition, future expectations, and transitional feeding needs.	Provides information from which client and SO can make informed choices. Knowledge of the interaction between malnutrition and illness is helpful in understanding need for special therapy.
Discuss reasons for use of nutrition support.	May experience anxiety regarding inability to eat and may not comprehend the nutritional value of the prescribed TPN or tube feedings.
Provide adequate time for teaching client and SO when client is going home on enteral or parenteral feedings. Document client's and SO's understanding, ability, and competence to deliver safe home therapy.	Generally, 3 to 4 days is sufficient for client and SO to become proficient with tube feedings. Parenteral therapy is more complex, and client and SO may require a week or longer to feel ready for home management; follow-up in the home is required.
Discuss proper handling, storage, and preparation of nutritional solutions; also discuss aseptic or clean techniques for care of insertion sites and use of dressings.	Reduces risk of formula or solution-related problems, metabolic complications, and infection.
Review use and proper care of nutritional delivery devices.	Client understanding and cooperation are key to the safe insertion and maintenance of nutritional support access devices and prevention of complications.
Review specific precautions (depending on type of feeding), such as checking placement of tube, sitting upright for enteral feeding, maintaining patency of tube, anchoring of tubing, and adequate length of tubing for nighttime feeding.	Promotes safe self-care and reduces risk of complications.
Discuss and demonstrate reinsertion of enterostomal feeding tube, if appropriate.	Tube may be changed routinely or inserted only for feedings. Intermittent feedings enhance client mobility and aid in transition to regular feeding pattern.
Identify signs and symptoms requiring medical evaluation—nausea and vomiting, abdominal cramping or bloating, diarrhea, rapid weight changes, erythema, drainage, foul odor at tube insertion site, fever and chills, coughing and choking, or difficulty breathing during enteral feeding.	Early evaluation and treatment of problems such as feeding intolerance, infection, and aspiration may prevent progression to complications that are more serious.
Instruct client and SO in glucose monitoring, if indicated.	Timely recognition of changes in blood glucose levels reduces risk of hyperglycemic or hypoglycemic reactions in client on TPN.
Discuss signs, symptoms, and treatment of hyperglycemia and hypoglycemia.	Hyperglycemia is more common for clients receiving parenteral feedings and those who have pancreas or liver disease or are taking large doses of corticosteroids. Rebound hypoglycemia can occur when feedings are intentionally or accidentally discontinued.

(continues on page 540)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Encourage use of diary for recording test results, physical feelings and any reactions, activity level, oral intake if any, I&O, and weekly weight. Report trends to appropriate healthcare providers.	Provides resource for review by healthcare providers for optimal management of individual situation. Note: Journaling (by client or caregiver) about intake may be especially important when efforts are being made to transition from enteral or parenteral feeding to oral feeding. Note: The client with conditions interfering with oral intake (e.g., stroke or Parkinson's disease; brain injury; facial trauma, burns) may require additional referrals and interventions by healthcare providers to manage nutrition needs.
Recommend daily exercise and activity to tolerance, scheduling of adequate rest periods.	Enhances gastric motility for enteral transition feedings, promotes feelings of general well-being, and prevents undue fatigue.
Ascertain that all supplies are in place in the home before discharge; make arrangements as needed with suppliers, such as hospital, pharmacy, medical equipment company, and laboratory.	Provides for successful, smooth transition from acute care setting to home and competent home therapy.
Refer to nutritional support team, home healthcare agency, and counseling resources. Provide with immediate-access phone numbers.	Client and SO need readily available support persons to assist with nutrition therapy, equipment problems, and emotional adjustments in long-term or home-based therapy.

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

- **Fatigue**—disease states; malnutrition; stress; altered body chemistry (e.g., medications, chemotherapy)
- **risk for Injury**—physical (e.g., catheter-related complications—catheter breaks, dislodgement, occlusion air emboli, septic thrombo-phlebitis); malnutrition; effects of therapy, drug interactions
- **risk for Infection**—invasive tubes, environmental exposure, malnutrition, chronic disease
- **interrupted Family Processes**—situational crises; shift of health status of a family member; shift in family roles

# Diseases of the Blood/ Blood-Forming Organs

## ANEMIAS—IRON DEFICIENCY, ANEMIA OF CHRONIC DISEASE, PERNICOUS, APLASTIC, HEMOLYTIC

**I. Pathophysiology**—decreased number of circulating red blood cells (RBCs), due to blood loss, increased destruction of RBCs (hemolysis), or decreased production of RBCs, resulting in diminished oxygen-carrying capacity of the blood (Maakaron et al, 2016)

- a. Iron deficiency anemia (ID): inadequate iron stores, which results in insufficient hemoglobin (Hgb) (key molecule in RBCs), causing cells to appear abnormal, unusually small (microcytic), and pale (hypochromic)
  - b. Anemia of chronic disease (ACD): Common conditions associated with ACD may include *infections* (e.g., human immunodeficiency virus [HIV], tuberculosis [TB], sepsis, osteomyelitis), *inflammation* (e.g., arthritis, inflammatory bowel disease), and *malignancies* (e.g., carcinomas, myeloma, lymphoma) (Betcher et al, 2015; Schrier & Camaschella, 2016).
  - c. Pernicious anemia (PA): Lack of intrinsic factor in the stomach results in inability to absorb vitamin B<sub>12</sub>, causing abnormal RBC formation.
  - d. Aplastic anemia: failure of bone marrow to produce cells, including RBCs and white blood cells (WBCs) and platelets
  - e. Hemolytic anemia: premature destruction of RBCs
- II. Etiology** (Maakaron et al, 2016; National Institutes of Health [NIH], 2012)
- a. Three main causes of anemia exist. They are:
    - i. Blood loss (acute or chronic)
    - ii. Decreased RBC production as may occur with (1) defect in stem cells (e.g., aplastic anemia), defect in heme (see Glossary) production (e.g., iron deficiency, thalassemias), and (3) defective DNA production
    - iii. Increased RBC destruction caused by (1) external factors, (2) hereditary internal factors, and (3) acquired defects
    - iv. Within these causes, there are a number of specific etiologies. Some examples of these specifics include (1) genetics (e.g., thalassemias, Fanconi anemia); (2) nutritional (e.g., iron deficiency, vitamin B<sub>12</sub> and folate deficiency; starvation and malnutrition); (3) physical (e.g., trauma, burns, frostbite, prosthetic valves); (4) chronic disease and malignancies (e.g., kidney and liver disease, chronic infections, neoplasms); (5) infectious: viral (e.g., hepatitis), bacterial (e.g., gram-negative sepsis, *Clostridia*), and protozoal (e.g., malaria, toxoplasmosis); (6) drugs or chemicals (common cause of aplastic and hypoplastic disorders) and bone marrow suppression (e.g., antibiotics, anticonvulsants); and (7) active bleeding (e.g., trauma, ulcers, varices, use of medications such as nonsteroidal anti-inflammatory drugs [NSAIDs] or warfarin).
  - b. Adult anemia is usually defined as an Hgb level lower than 11 g/dL, with severe anemia defined as an Hgb lower than 8 g/dL. Not all sources agree with these numbers. For example, Maakaron opines that anemia is defined by the lower limits set for the Hgb range and that “the World Health Organization (WHO) chose 12.5 g/dL for both adult males and females. In the United States, limits of 13.5 g/dL for men and 12.5 g/dL for women are probably more realistic” (Maakaron et al, 2016).
  - c. Anemia is a common condition, occurring in all age groups, both male and female (although incidence is twice as prevalent in females), and in all races and ethnic groups. Certain races and ethnic groups have an increased prevalence of genetic anemias (e.g., sickle cell anemia has greater morbidity and mortality in African Americans than in general population) (Maakaron et al, 2016).
  - d. Anemias are associated with many physiological complications, including dyspnea, fatigue, dizziness, decreased cognition, impaired sleep, sexual dysfunction, and significant debilitation. The most serious complications of severe anemia arise from tissue hypoxia such as may occur in shock or coronary and pulmonary insufficiency.
  - e. ID
    - i. Most frequently occurring form of anemia
    - ii. Lack of iron in the body due to a variety of causes (Nabili, 2016)
      - 1. Blood loss due to disease, such as gastric or duodenal ulcers, diverticula, hemorrhoids, ulcerative colitis; injury or trauma; or certain medications, including aspirin or nonsteroidal anti-inflammatory drugs (NSAIDs)
      - 2. Inadequate nutrition, such as not eating enough foods that contain iron

(continues on page 542)

- 3. Malabsorption syndromes, such as not utilizing iron from food that is eaten
  - 4. Lead exposure
  - f. ACD
    - i. Primarily due to slowed production of RBCs as a result of low reticulocyte production
    - ii. Develops slowly and is only evident after time
    - iii. Symptoms are usually associated with the disease causing the anemia rather than the anemia itself. Examples are the anemias associated with chronic kidney disease, chronic malnutrition, or cancers (Nabili, 2016).
    - iv. Second most prevalent form of anemia.
  - g. PA—an autoimmune disorder
    - i. Characterized by the production of autoantibodies to gastric parietal cells and their secretory product—*intrinsic factor*—which is needed for vitamin B<sub>12</sub> absorption
    - ii. Conditions that interfere with the body's absorption and use of B<sub>12</sub> include Crohn's and Whipple's diseases, gastrectomy or gastric bypass, and the use of chemotherapeutic medications.
  - h. Aplastic anemia—bone marrow failure
    - i. May be associated with conditions that affect erythropoietin production and secretion, such as certain cancers and cancer treatments and renal, hepatic, or endocrine disorders
    - ii. Other known causes include exposure to chemicals, such as benzene, insecticides, solvents; certain drugs, such as chemotherapy, gold, seizure medications, some antibiotics; viruses, such as HIV, Epstein-Barr; immune conditions, such as systemic lupus erythematosus, rheumatoid arthritis; radiation; and certain inherited disorders, such as Fanconi's anemia.
- i.** Hemolytic anemia—marked by an accelerated destruction of RBCs
- i. Several types of hemolytic anemias, including sickle cell anemia (Maakaron & Taher, 2017; Nabili, 2016). (See CP: Sickle Cell Crisis.)
  - ii. Causes include hereditary factors; blood transfusion reactions; immune disorders, acute viral or infectious agents; certain drugs, such as quinidine, penicillin, and methyldopa; and toxins, such as chemicals and venoms.
- III. Statistics**
- a. Morbidity: The most serious complications of severe anemia arise from tissue hypoxia. Shock, hypotension, or coronary and pulmonary insufficiency can occur. In a study conducted between 2009 and 2011, 152,757 (72%) of hospitalization discharge diagnoses contained the condition “anemia,” with 17% of those classified as severe. Discharge anemia was associated with severity-dependent increased odds for 30-day hospital readmission compared with those without anemia (Koch et al, 2014).
  - b. Mortality: 5219 people died of anemia during 2014 in the United States according to the Centers for Disease Control and Prevention (CDC), National Center for Health Statistics. Persons with sickle cell anemia (Hgb SS) have the worst prognosis, since they have more frequent crises. The 2-year fatality rate for severe aplastic anemia is 70% without bone marrow transplantation or a response to immunosuppressive therapy. Untreated hemolytic-uremic syndrome carries a 40% mortality rate (CDC, 2014; Maakaron et al, 2016).
  - c. Cost: Because anemia rarely stands on its own and is listed as one diagnosis among others in many chronically ill patients with a variety of diseases, direct care costs are difficult to determine.

## G L O S S A R Y

**Acquired anemia:** Client is not born with anemia but develops it. Includes conditions and factors that can lead to anemia, such as poor diet, abnormal hormone (erythropoietin) levels, bone marrow suppression due to cancer treatment, certain medications and toxins, and pregnancy. Some anemias are mixed acquired and inherited (e.g., aplastic).

**Cheilitis:** Inflammation of the lips with cracking at the corners of the mouth.

**Echymosis:** Superficial bleeding (bruising) under the skin or mucous membrane.

**Erythropoiesis:** Red blood cell (RBC) production in the bone marrow.

**Glossitis:** Inflammation of tongue.

**Hematemesis:** Bloody vomitus.

**Hematinic:** An agent that improves the quality of blood by stimulating RBC production erythrocytes and/or the hemoglobin concentration. Examples include iron preparations and the B complex vitamins.

**Heme:** The nonprotein, insoluble, iron compound, and constitutes the pigment portion or protein-free part of the hemoglobin molecule and is responsible for its oxygen-carrying properties.

**Inherited anemia:** Gene for certain anemia is passed on by parents. Anemias of this type include sickle cell, thalas-

semia, Fanconi, and others. Some anemias are mixed acquired and inherited (e.g., aplastic).

**Koilonychia:** Dystrophy of the nails, resulting in thinning and concave or spoon shape.

**Lymphadenopathy:** Enlargement of the lymph nodes.

**Macrocytic anemia:** The red blood cells are larger than normal. Major causes of this type are pernicious anemia and anemia related to alcoholism (Nabali, 2016).

**Melena:** Black, tarry stools due to digested blood in the gastrointestinal (GI) tract.

**Microcytic anemia:** The red blood cells are smaller than normal. The major causes of this type are iron deficiency anemia and thalassemia (inherited disorders of hemoglobin).

**Normocytic anemia:** The red blood cells are normal in size but low in number. This type of anemia accompanies chronic diseases and kidney disorders.

**Petechiae:** Small, purplish, hemorrhagic spots on the skin.

**Pica:** Insatiable craving to eat nonfood items, such as starch, clay, crayons, and paper.

**Red blood cell characterization of anemias:** Based on the mean corpuscular volume (MCV), or average RBC size, reported in the complete blood count (CBC) test:

- (1) *microcytic*: most commonly caused by iron deficiency; other causes include thalassemia, anemia of

**G L O S S A R Y** (continued)

chronic disease, and sideroblastic anemia; (2) *normocytic*: may be caused by hemorrhage, hemolysis, bone marrow failure, anemia of chronic inflammation, or renal insufficiency; and (3) *macrocytic*: the larger red cells are always associated with insufficient numbers of cells and often also insufficient hemoglobin content per cell. Most are megaloblastic (cells are larger because they cannot produce DNA quickly enough to divide at the right time) and include vitamin B<sub>12</sub> or folate deficiencies

caused by insufficient uptake or inadequate absorption through lack of intrinsic factor (pernicious anemia) (Rogers et al, 2012).

**Romberg's sign:** Inability to maintain body balance when eyes are shut and feet are close together, sometimes noted with movement disorders accompanying pernicious anemia.

**Stomatitis:** Inflammation, ulceration of mucosal lining of any structures in the mouth.

**CARE SETTING**

Clients are treated at the community level except in the presence of severe cardiovascular or immune compromise. Although the medical treatments vary widely due to the many variations in anemia presentation, nursing care for the anemic client has a common theme: managing physical symptoms and maximizing quality-of-life issues.

**CLIENT ASSESSMENT DATABASE****DIAGNOSTIC DIVISION  
MAY REPORT****ACTIVITY/REST**

- Fatigue, weakness, general malaise
- Low exercise tolerance
- Greater need for rest and sleep

**MAY EXHIBIT**

- \*\*\*\*Note: Signs and symptoms listed here may be due to either the underlying disease or the anemia itself. For example, chronic kidney disease (CKD) and anemia of chronic disease (ACD) may present with very similar symptoms (Verma & Stein, 2017).
- Tachycardia and tachypnea, dyspnea on exertion or at rest (severe or aplastic anemia)
  - Muscle weakness and decreased strength
  - Slumping shoulders, drooping posture, slow walk, and other cues indicative of fatigue
  - Lethargy, withdrawal, apathy, lassitude, and lack of interest in surroundings

**CIRCULATION**

- Angina (particularly in elderly)
- Palpitations (compensatory tachycardia)
- Cold hands and feet
- Brittle nails
- History of chronic blood loss, such as chronic GI bleeding, heavy menses (ID)

- Tachycardia
- Systolic murmur (ID)
- Blood pressure (BP)—increased systolic with stable diastolic and a widened pulse pressure, postural hypotension
- Bounding pulse and throbbing carotid pulsations reflect increased cardiac output as a compensatory mechanism to provide oxygen and nutrients to cells.
- Dysrhythmias, electrocardiogram abnormalities—ST-segment depression and flattening or depression of the T wave, tachycardia

(continues on page 544)

<b>DIAGNOSTIC STUDIES</b>	
TEST	WHAT IT TELLS ME
<b>BLOOD TESTS</b>	
<ul style="list-style-type: none"> <li><b>Complete blood count (CBC):</b> Battery of screening tests, which typically includes hemoglobin, hematocrit; RBC count, morphology, indices, and distribution width index; platelet count and size; and WBC count and differential.</li> <li><b>Hemoglobin (Hgb):</b> The oxygen-carrying pigment and predominant protein in the RBCs.</li> </ul>	<p>Evaluates for known or suspected anemia. Types of anemias may be differentiated by the number of red blood cells as well as their color and shape. <i>Note:</i> Methods for measuring RBC mass are time-consuming and expensive. Thus, in practice, anemia is usually confirmed and expressed by measurement of the RBC count, Hgb concentration, and hematocrit (Hct) (Maakaron et al, 2016).</p> <p>Usual Hgb varies somewhat among healthy individuals, making a universal “normal” value elusive. For client with a known baseline level, a decrease of 2 g/dL or more is cause for concern and assessment. Both Hgb and Hct are decreased with blood loss and bone marrow suppression (Rogers et al, 2012).</p>

(continues on page 546)

## DIAGNOSTIC STUDIES (contd.)

WHY IT IS DONE (continued)	WHAT IT TELLS ME (continued)
<ul style="list-style-type: none"> <li>• <b>Hematocrit (Hct):</b> The proportion of packed RBCs to serum.</li>     <li>• <b>RBC (also called erythrocyte) count:</b> Number of RBCs per unit volume.</li> <li>• <b>Reticulocyte count:</b> Immature RBCs. Helps assess bone marrow function.</li> <li>• <b>RBC survival time:</b> Evaluates age of RBCs.</li>     <li>• <b>Erythrocyte fragility test:</b> Evaluates susceptibility of RBCs to breakdown (hemolysis) under certain conditions.</li> <li>• <b>Erythrocyte sedimentation rate (ESR):</b> Measures rate at which RBCs settle.</li>     <li>• <b>WBCs:</b> Total cell count and specific WBCs, called differential.</li> <li>• <b>Platelet count:</b> Platelets have essential function in coagulation.</li> <li>• <b>Erythropoietin:</b> Hormone that stimulates bone marrow to produce red blood cells.</li>     <li>• <b>Serum iron panel</b></li> <li>• <b>Serum iron:</b> Measures the level of iron in the liquid part of blood.</li>     <li>• <b>Total iron-binding capacity (TIBC):</b> Measures the amount of iron that can be carried through blood by transferrin.</li> <li>• <b>Serum ferritin:</b> Reflects the amount of stored iron in body.</li> <li>• <b>Vitamin B<sub>12</sub> (cobalamin) and folate (folic acid):</b> Measures the concentration of vitamin B<sub>12</sub> and folate in the serum. The amount of folate inside RBCs may also be measured; it will normally be at a higher concentration inside the cell than in the serum.</li> <li>• <b>Serum bilirubin:</b> Product that results from the breakdown of Hgb.</li> <li>• <b>Serum lactate dehydrogenase (LDH):</b> Serum LDH levels may occasionally be ordered to monitor damage caused by muscle trauma or injury and to help identify hemolytic anemia.</li> </ul>	<p>Aids in determining source of hemolytic anemia or anemias related to deficiencies in dietary intake or malabsorption. Sometimes used when a person has a family history of anemia; this test provides information on sickle cell anemia or thalassemia (Nabili, 2016).</p> <p>Decreased in ID and PA; severely decreased in aplastic anemia.</p> <p>Decreased in PA and aplastic anemia. Elevated in blood loss and hemolytic and compensated anemias.</p> <p>Useful in the differential diagnosis of anemias because RBCs have shortened life spans in pernicious and hemolytic anemias.</p> <p>Decreased in ID. **NURSING PRIORITIES**

1. Enhance tissue perfusion.
2. Provide nutritional and fluid needs.
3. Prevent complications.
4. Provide information about disease process, prognosis, and treatment regimen.

**DISCHARGE GOALS**

1. ADLs met by self or with assistance of others.
2. Complications prevented or minimized.
3. Disease process, prognosis, and therapeutic regimen understood.
4. Plan in place to meet needs after discharge.

**NURSING DIAGNOSIS:** **Activity Intolerance****May Be Related To**

Imbalance between oxygen supply and demand (anemia)

**Possibly Evidenced By**

Fatigue; generalized weakness  
Abnormal heart rate or blood pressure response to activity  
Electrocardiogram (ECG) change (e.g., arrhythmia, ischemia)  
Exertional discomfort; dyspnea

**Desired Outcomes/Evaluation Criteria—Client Will****Endurance NOC**

Report a measurable increase in activity tolerance, including performance of ADLs.

Demonstrate reduced physiological signs of intolerance—pulse, respirations, and BP within client's normal range.

Display laboratory values (Hgb/Hct) within acceptable range.

**ACTIONS/INTERVENTIONS****RATIONALE****Energy Management NIC***Independent*

Assess client's ability to perform normal tasks and ADLs, noting reports of weakness, fatigue, and difficulty accomplishing tasks.

Influences choice of interventions and needed assistance.

Note changes in balance, gait disturbance, and muscle weakness.

May indicate neurological changes associated with vitamin B<sub>12</sub> deficiency, affecting client safety and increasing risk of injury.

Monitor BP, pulse, and respirations during and after activity.  
Note adverse responses to increased levels of activity—increased heart rate and BP, dysrhythmias, dizziness, dyspnea, tachypnea, and cyanosis of mucous membranes and nailbeds.

Cardiopulmonary manifestations result from attempts by the heart and lungs to supply adequate amounts of oxygen to the tissues.

Recommend frequent rest periods or bedrest (rare), as indicated.

Activity may need to be curtailed until severe anemia is at least partially corrected to lower body's oxygen requirements and reduce strain on the heart and lungs.

Elevate head of bed, as tolerated.

Enhances lung expansion to maximize oxygenation for cellular uptake. Note: May be contraindicated if hypotension is present.

Suggest client change position slowly; monitor for dizziness.

Postural hypotension or cerebral hypoxia may cause dizziness, fainting, and increased risk of injury.

Assist client to prioritize ADLs and desired activities.  
Alternate rest periods with activity periods.

Promotes adequate rest, maintains energy level, and alleviates strain on the cardiac and respiratory systems.

Provide or recommend assistance with activities and ambulation as necessary, allowing client to be an active participant as much as possible.

Although help may be necessary, self-esteem is enhanced when client does some things for self.

Plan activity progression with client, including activities that client views as essential. Increase activity levels, as tolerated.

Promotes gradual return to a more normal activity level and improved muscle tone and stamina. Increases self-esteem and sense of control.

Identify and implement energy-saving techniques: shower chair and sitting to perform tasks.

Encourages client to do as much as possible, while conserving limited energy and preventing fatigue.

(continues on page 548)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Instruct client to stop current activity if palpitations, chest pain, shortness of breath, weakness, or dizziness occur.	Cellular ischemia potentiates risk of infarction, and excessive cardiopulmonary strain and stress may lead to decompensation and failure.
Discuss importance of maintaining environmental temperature and body warmth, as indicated.	Vasoconstriction with shunting of blood to vital organs decreases peripheral circulation, impairing tissue perfusion. Client's comfort and need for warmth must be balanced with need to avoid excessive heat with resultant vasodilation, which reduces organ perfusion.
<b>Collaborative</b> Monitor laboratory studies, such as Hgb/Hct, RBC count, and arterial blood gases (ABGs).	Identifies deficiencies in RBC components affecting oxygen transport, treatment needs, and response to therapy.
Provide supplemental oxygen as indicated.	Maximizing oxygen transport to tissues improves ability to function.
Collaborate in treatment of underlying condition(s):	
Administer the following, as indicated:	
Whole blood, packed RBCs (PRCs); blood products (fresh-frozen plasma [FFP], platelets, blood factors) as indicated for the client's particular needs. Monitor closely for reactions during blood transfusion.	Increases number of oxygen-carrying cells; corrects deficiencies to reduce risk of hemorrhage in acutely compromised individuals. Transfusions are reserved for severe blood loss anemias with cardiovascular compromise and are used after other therapies have failed to restore homeostasis. Note: Packed red blood cells (PRBCs) are preferred over whole blood since they reduce complications associated with volume overload, immunogenic reactions, and storage. The American Association of Blood Banks (AABB) and The Joint Commission (TJC) have recommended restrictive transfusion practices (hemoglobin 7–8 g/dL) in stable hospitalized patients considering symptoms and not just Hgb levels in transfusion decisions. Additional AABB recommendations include avoiding blood products in hemodynamically stable patients with ID, using blood products to reverse warfarin only if a patient has serious bleeding or requires emergency procedures, and avoiding serial blood counts in stable patients (AABB, 2014; The Joint Commission, 2011).
Erythropoiesis-stimulating agents (ESAs), such as epoetin-Alpha (Procrit, EpoGen [EPO]; darbepoetin [Aranesp]); peginesatide (Omontys), methoxy polyethylene glycol-epoetin beta (Micera)	ESAs have been shown to be effective in increasing erythrocyte and Hgb levels and reducing need for RBC transfusions in many clients with anemia of chronic disease, including kidney failure in patients on dialysis. Note: Concerns have been raised about side effects of ESAs and other health risks (e.g., thromboembolic phenomena, tumor progress in cancer, and increased mortality), and research continues (Drugs.com, 2015, 2017; Schrier et al, 2017).
Iron preparations, such as IV iron dextran complex (INFeD), ferinject (Injectafer), or oral iron (e.g., ferrous sulfate [Fer-Iron, Slow-FE] or carbonyl iron [Fesol, Iron Chews]), as indicated	The appropriate treatment of anemia due to blood loss is correction of the underlying condition and oral administration of iron preparations until the anemia is corrected and for several months afterward to ensure that body stores are replete with iron (Maakaron et al, 2016). Note: Certain populations are at sufficiently high risk for iron deficiency to warrant prophylactic iron therapy. These include anemia in pregnant women, women with menorrhagia, and consumers of a strict vegetarian diet (Fernández-Gaxiola & De-Regil, 2011).
Vitamins such as cyanocobalamin (also called vitamin B <sub>12</sub> [Ener-B, Calo-Mist]), folic acid (Folvite), and vitamin K	Vitamins help to correct deficiencies and promote protein synthesis.

**ACTIONS/INTERVENTIONS (continued)**

Prepare for surgical/other procedures, if indicated.

**RATIONALE (continued)**

Surgery is useful to control bleeding in clients who are anemic because of bleeding, such as in ulcers and uterine bleeding, or to remove spleen as treatment of autoimmune hemolytic anemia. Bone marrow and stem cell transplantation may be done in the presence of bone marrow failure—aplastic anemia.

**NURSING DIAGNOSIS: imbalanced Nutrition: less than body requirements****May Be Related To**

Failure to ingest or inability to digest food or absorb nutrients  
Biological factors

**Possibly Evidenced By**

Food intake less than recommended daily allowances  
Weight loss or weight below ideal range; insufficient muscle tone  
Abnormal laboratory studies

**Desired Outcomes/Evaluation Criteria—Client Will****Nutritional Status NOC**

Demonstrate normalization of laboratory values.  
Be free of/experience improvement in signs of malnutrition.  
Verbalize understanding of causative factors when known and needed interventions to prevent complications.

**ACTIONS/INTERVENTIONS****RATIONALE****Nutrition Therapy NIC****Independent**

Review nutritional history, including food preferences.

Identifies deficiencies and suggests possible interventions.  
Note: Daily meal diary over period of time may be necessary to identify anemia related to nutrient deficiencies such as no meat in diet—iron and vitamin B<sub>12</sub> deficiency, or few leafy vegetables in diet—folic acid deficiency.

Observe and record client's food intake.

Monitors caloric intake or insufficient quality of food consumption.

Weigh periodically as appropriate, such as weekly.

Monitors weight loss and effectiveness of nutritional interventions.

Recommend small, frequent meals and between-meal nourishment.

May enhance intake while preventing gastric distention. Use of liquid supplements such as Ensure, Boost, or similar product provides additional protein and calories.

Suggest bland diet, low in roughage, avoiding hot, spicy, or very acidic foods, as indicated.

When oral lesions are present, pain may restrict type of foods client can tolerate.

Have client record and report occurrence of nausea or vomiting, flatus, and other related symptoms, such as irritability or impaired memory.

May reflect the effects of anemias (e.g., hypoxia or vitamin B<sub>12</sub> deficiency) on body organs and systems.

Encourage or assist with oral hygiene; use soft-bristled toothbrush for gentle brushing. Provide dilute, alcohol-free mouthwash if oral mucosa is ulcerated.

Diminishes bacterial growth, minimizing possibility of infection. Special mouth-care techniques may be needed if tissue is fragile, ulcerated, or bleeding and pain is severe.

**Collaborative**

Consult with nutritionist/dietitian.

Aids in establishing dietary plan to meet individual needs.

Monitor laboratory studies, such as Hgb/Hct, blood urea nitrogen (BUN), prealbumin and albumin, protein, transferrin, serum iron, vitamin B<sub>12</sub>, folic acid, TIBC, and serum electrolytes.

Evaluates effectiveness of treatment regimen, including dietary sources of needed nutrients.

(continues on page 550)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Administer medications, as indicated, for example:	
Vitamin and mineral supplements, such as cyanocobalamin (vitamin B <sub>12</sub> ), folic acid (Folvite), and ascorbic acid (vitamin C)	Replacements needed depend on type of anemia and presence of poor oral intake and identified deficiencies.

NURSING DIAGNOSIS: <b>risk for Infection</b>
<b>Possibly Evidenced By</b>
Malnutrition; alteration in skin integrity; stasis of body fluids; invasive procedures
Chronic disease; decrease in hemoglobin, leukopenia, decrease in granulocytes; suppressed inflammatory response
<b>Desired Outcomes/Evaluation Criteria—Client/Caregiver Will</b>
<b>Risk Control NOC</b>
Identify behaviors to prevent and reduce risk of infection.
<b>Infection Severity NOC</b>
Be free of signs of infection; achieve timely wound healing if present.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Infection Protection NIC</b>	
<i>Independent</i>	
Perform and promote meticulous handwashing by caregivers and client.	Prevents cross-contamination or bacterial colonization. Note: Client with severe or aplastic anemia may be at risk from normal skin flora.
Maintain strict aseptic techniques with procedures and wound care.	Reduces risk of bacterial colonization and infection.
Provide meticulous skin, oral, and perianal care.	Reduces risk of skin or tissue breakdown and infection.
Encourage frequent position changes and ambulation, coughing, and deep-breathing exercises.	Promotes ventilation of all lung segments and aids in mobilizing secretions to prevent pneumonia.
Promote adequate fluid intake.	Assists in liquefying respiratory secretions to facilitate expectoration and prevent stasis of body fluids in lungs and bladder.
Emphasize need to monitor and limit visitors, as indicated. Provide protective isolation, if appropriate. Restrict live plants and cut flowers.	Limits exposure to infectious agents. Protective isolation may be required in aplastic anemia, when immune response is most compromised.
Monitor temperature. Note presence of chills and tachycardia with or without fever.	Reflective of inflammatory process or infection, requiring evaluation and treatment. Note: With bone marrow suppression, leukocytic failure may lead to fulminating infections.
Observe for wound erythema and drainage.	Indicators of local infection. Note: Pus formation may be absent if granulocytes are depressed.
<i>Collaborative</i>	
Obtain specimens for culture and sensitivity, as indicated.	Verifies presence of infection, identifies specific pathogen, and influences choice of treatment.
Administer topical antiseptics and systemic antibiotics.	May be used prophylactically to reduce colonization or used to treat specific infectious process.

<b>NURSING DIAGNOSIS:</b> <b>deficient Knowledge regarding condition, prognosis, treatment, self-care, prevention of crisis, and discharge needs</b>	
<b>May Be Related To</b> Insufficient information or knowledge of resources; misinformation presented by others Alteration in cognitive functioning or memory	
<b>Possibly Evidenced By</b> Insufficient knowledge Inaccurate follow-through of instructions Development of preventable complications	
<b>Desired Outcomes/Evaluation Criteria—Client Will</b>	
<p><b>Self-Management: Chronic Anemia [NOC]</b></p> <p>Verbalize understanding of the nature of the disease process, causative factors, diagnostic procedures, and potential complications.</p> <p>Verbalize understanding of therapeutic needs.</p> <p>Initiate necessary behaviors or lifestyle changes and participate in treatment regimen.</p>	
ACTIONS/INTERVENTIONS	RATIONALE
<b>Teaching: Disease Process [NIC]</b>	
<i>Independent</i>	
Provide information about specific anemia and explain that therapy depends on the type and severity of the anemia.	Provides knowledge base from which client can make informed choices. Allays anxiety and may promote cooperation with therapeutic regimen to manage a condition that may be long-lasting.
Discuss effects of anemias on preexisting conditions.	Anemia aggravates many underlying conditions, and resolution of anemia is impacted by aging and developmental issues, nutritional and socioeconomic issues, and acute and chronic conditions.
Review purpose and preparations for diagnostic studies.	Knowledge of what to expect can diminish anxiety.
Explain that blood taken for laboratory studies typically does not worsen anemia.	This is often an unspoken concern that can potentiate client's anxiety. Note: For the vast majority of hospitalized clients, the blood loss associated with diagnostic testing is of little or no clinical significance. However, studies have confirmed that anemia is a common feature of critical illness, developing in 90% of clients by the third day following admission to intensive care. For around a half of these individuals, anemia is of sufficient severity ( $<9$ g/dL) to warrant red cell transfusion (Corwin et al, 2004; Tinmouth et al, 2008).
Review required diet alterations to meet specific dietary needs, as determined by type of anemia and deficiency.	Red meat, liver, seafood, green leafy vegetables, whole wheat bread, and dried fruits are sources of iron. Green vegetables, whole grains, liver, and citrus fruits are sources of folic acid and vitamin C, which enhance absorption of iron.
Discuss foods to avoid, such as coffee, tea, egg yolks, milk, fiber, and soy protein, at the time when client is eating high-iron foods.	These foods block absorption of iron and should be taken at a different meal. For example, red meat and milk taken at the same time can block absorption of the iron from the meat.
Assess resources, including financial, and ability to obtain, store, and prepare food.	Inadequate resources may affect ability to purchase and prepare appropriate food items.
Refer to appropriate community resources when indicated, such as social services for food stamps and Meals on Wheels.	May need assistance with groceries and meal preparation.
Encourage cessation of smoking.	Smoking decreases available oxygen and causes vasoconstriction.

(continues on page 552)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Suggest use of protective devices, such as sheepskin, egg-crate, alternating air pressure, or water mattress; heel and elbow protectors; and pillows, as indicated.	Avoids skin breakdown by preventing or reducing pressure against skin surfaces.
Review good oral hygiene and necessity for regular dental care.	Effects of anemia such as oral lesions and use of iron supplements increase risk of infection and bacteremia.
Emphasize importance of reporting signs of fatigue, weakness, paresthesias, irritability, and impaired memory.	Indicates that anemia is progressing or failing to resolve, necessitating further evaluation and treatment changes.
<b>Teaching: Prescribed Medication NIC</b> <b>Collaborative</b>	
Provide information about purpose, dosage, schedule, precautions, and potential side effects, interactions, and adverse reactions to all prescribed medications.	Information enhances cooperation with regimen. Recovery from anemias can be slow, requiring lengthy treatment and prevention of secondary complications.
For the client on iron preparations:	
Discuss importance of taking only prescribed dosages.	Overdose of iron medication can be toxic.
Advise taking with meals or immediately after meals.	Iron is best absorbed on an empty stomach. However, iron salts are gastric irritants and can cause dyspepsia, diarrhea, and abdominal discomfort if taken on an empty stomach.
Discuss possibility of iron infusions and refer to healthcare provider.	Depleted iron stores may be best treated in this manner, if client is not responding or is intolerant of oral or injected iron preparations.
Instruct to avoid use of aspirin and other NSAIDs.	Increases bleeding tendencies.

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

- **Activity Intolerance**—imbalance between oxygen supply and demand
- **imbalanced Nutrition: less than body requirements**—failure to ingest or inability to digest food or absorb nutrients
- **risk for Infection**—inadequate secondary defenses (e.g., decreased hemoglobin, leukopenia, or decreased granulocytes, suppressed inflammatory response); inadequate primary defenses (e.g., broken skin, stasis of body fluids; invasive procedures); chronic disease; malnutrition
- **ineffective Health Management**—economic difficulties, perceived benefits/susceptibility, insufficient social support

## SICKLE CELL CRISIS

### I. Pathophysiology

- a. Sickle cell disease (SCD) is a severe hereditary form of anemia in which a mutated form of hemoglobin (called hemoglobin S or sickle hemoglobin) causes the red blood cells to change shape (sickle). The sickled cells can clump together inside cells and blood vessels, obstructing blood flow and causing tissue ischemia, which can progressively damage and destroy vital organs (Maakaron & Taher, 2017; NIH, 2017).
- b. After recurrent episodes of sickling, membrane damage occurs and the cells are no longer capable of resuming their normal shape upon reoxygenation. The resulting anemia (termed *sickle cell anemia*) is chronic and hemolytic in nature.
- c. *Sickle cell crisis* is a broad term that describes several different conditions, such as (1) aplastic crisis (temporary bone marrow failure), (2) hemolytic crisis (acute red cell destruction, leading to jaundice), and (3) vaso-occlusive

crisis (VOC) (sudden, severe pain due to infarctions in the bones, organs, or nervous system). Conditions that can trigger a VOC include infection, pregnancy, alcohol or tobacco use, exposure to temperature extremes, dehydration, exposure to high altitude, and extreme physical or psychological stress, although a cause is not always identified. **P** VOC episodes can occur from the first year of life onward (Vacca & Blank, 2017).

### II. Etiology

- a. Sickle hemoglobinopathies compose a group of genetic diseases, consisting of four genotypes: sickle cell anemia (HbSS), sickle hemoglobin C disease (HbSC), and the sickle cell thalassemias ( $S\beta^+$ - and  $S\beta^0$ -thalassemia) (Ellison, 2012). The different forms of sickle cell disease are determined by the combination of genes inherited from the person's parents.
- b. Vaso-occlusion can be caused by infections, dehydration, stress, exercise, temperature extremes, and smoking,

associated with hypoxia and acidosis, inflammation, ischemia, and tissue infarction, and is responsible for a wide variety of the clinical complications of SCD (Vacca & Blank, 2017).

### III. Complications

- i. Painful episodes are the most common complication of SCD, often in extremities, ribs, sternum, vertebral column, or abdomen (Ohene-Frempong & Gupta, 2015).
- ii. Central nervous system: The most severe manifestation is stroke. Cerebrovascular accidents (24% of people with sickle cell disease [SCD] have a stroke by the age of 45 years) (Verduzco & Nathan, 2009). Ischemic strokes are more common in children and older adults and are less common in adults ages 20 to 29 (Yawn et al, 2014).
- iii. Lymphatic system: Splenic sequestration happens when a lot of sickled RBCs become trapped in the spleen. In most older children and adults with HgSS disease, the repetitive RBC sickling in the spleen eventually results in scarring, fibrosis, and a nonfunctional spleen (called autosplenectomy). Acute splenic sequestration (ASS) is a sudden life-threatening pooling of large amounts of blood in the spleen, leading to acute splenomegaly, profound anemia, and, in severe cases, hypovolemic shock. Death may occur in a few hours.
- iv. Cardiopulmonary system: There are several manifestations, including increased airway reactivity, nocturnal oxygen desaturation, increased risk of pneumonias, pulmonary embolism (PE), acute chest syndrome (ACS), sickle cell chronic lung disease (SCCLD), and pulmonary hypertension. Acute chest syndrome is a sudden-onset pulmonary condition that affects about 12% of adults but is more common in children (about 25%) (Meier & Miller, 2012). **P** In children below 9 years of age, infection is a more common etiology for ACS than in older children or adults (Heeney & Mahoney, 2015). ACS is defined in severity categories (mild to very severe), and the severity categories apply equally to adults and children (Field & DeBaun, 2017). Pulmonary hypertension is emerging as a relatively common complication and is one of the leading causes of morbidity and mortality in adults with SCD. Various studies have found that more than 40% of adults with SCD have pulmonary hypertension that worsens with age (Dahoui et al, 2010; Maakaron & Taher, 2017).
- v. Sexual and reproductive manifestations: Infertility in men with SCD appears to have multiple causes, including hypogonadism, sperm abnormalities, and erectile dysfunction (ED) due to priapism. In females, infertility may be a problem (studies not conclusive); however, onset of menses is often delayed, and menstrual bleeding is associated with increased SCD-related pain (Smith-Whitley, 2014). Mother/baby: There is a high risk of fetal loss due to spontaneous abortion. Placenta previa and abruption are common due to hypoxia and placental infarction. **P** At birth, the infant often is premature or has low birth weight (Maakaron & Taher, 2017).
- vi. Gastrointestinal and hepatic systems: **P** Cholelithiasis is common, especially in children. The spleen is

almost always involved in SCD and (**P** often infarcted within the first 18 to 36 months of life, paralleling the disappearance of protective Hb F, resulting in hyposplenism or asplenia; liver dysfunction is common (many develop chronic hepatitis [B or C], acute sickle hepatic crisis, iron overload, pigment stones, and cirrhosis with liver failure) (Banerjee & DeBaun, 2016).

- vii. Genitourinary involvement: Kidneys can lose ability to concentrate. The prevalence of albuminuria and proteinuria is 30% within the first 3 decades of life and increases up to 70% in older patients. The development of nephrotic syndrome has been linked to progression to acute and chronic renal failure (Pham et al, 2000). **P** Renal function is usually normal during adolescence but frequently becomes subnormal as chronic kidney disease progresses. The kidneys eventually shrink, and the capsular surface becomes grossly distorted and scarred.
- viii. Dermatologic involvement: Ischemic ulcers in extremities are due to arterial occlusion (either micro- or macro-occlusion) and can be a chronic, painful problem.
- ix. **P** In addition to any of the complications that adults can have, children also may experience growth retardation, delayed sexual maturation, and being underweight (Maakaron & Taher, 2017). Dactylitis (hand-foot syndrome): Major and unresolved swelling of hands or feet is often first symptom noted in children (Pack-Mabien & Haynes, 2009).

### IV. Statistics

- a. Morbidity: Sickle cell disease is the most common inherited blood disorder in the United States. Although figures vary somewhat, SCD is occurring in approximately 1 in 365 black or African American births and 1 in 1400 Hispanic American births (NIH, 2017). It is believed there are approximately 100,000 people living with SCD in the United States (CDC, 2016; Maakaron & Taher, 2017).
- b. Mortality: Median survival rate for individuals with SCD is 48 years for women and 42 years for men (Maakaron & Taher, 2017). Acute chest syndrome (ACS) is the most common cause of death (Maakaron & Taher, 2017). **P** Mortality rates for sickle cell–related death among black or African American children (younger than 4 years of age) fell by 42% from 1999 through 2002. This drop coincided with the introduction in 2000 of a vaccine that protects against invasive pneumococcal disease (CDC, 2016). In the same time period, the age groups with the highest mortality were 35 to 44 years (males) and 45 to 54 years (females); however, there was a tendency for longer survival than in the previous decade (Hamideh & Alvarez, 2013; Heeney & Mahoney, 2015).
- c. Cost: In 2009, approximately \$1.1 billion was spent for treatment of sickle cell anemia, with roughly 80% of that amount spent for hospital costs (ReutersHealth, 2009). For an average patient with SCD reaching age 45, total lifetime healthcare costs were estimated to be \$953,640 per person (Kauf et al, 2009). \*\*\*It is likely that future costs will be greatly impacted by clinical trials for stem cells and biomodifier medications.

## G L O S S A R Y

**Acute chest syndrome (ACS):** A life-threatening complication defined as an infiltrate on a chest x-ray, accompanied by two or more other symptoms, which can include fever, cough, wheezing, tachypnea, or chest pain (reflects the unique nature of acute pulmonary illness in client with SCD).

**Dactylitis:** Swollen, tender digits of the hands and feet, causing severe pain. Often first sign of sickle cell disease in babies.

**Genetic disease:** The ultimate unit of inheritance, carried by the chromosome. Genes determine various characteristics, such as hair texture, skin color, height, shape of nose, lips, and so on, including the kind of hemoglobin in red blood cells (RBCs).

**Hemoglobin (Hgb):** An iron-containing protein of the RBC, which carries oxygen to the tissues and gives the cell its red color.

**Hemolysis:** Destruction of RBCs and subsequent release of hemoglobin.

**Hyperhemolytic crisis:** A rapid, higher-than-normal rate of hemolysis; reticulocytes are increased in peripheral blood, and bone marrow is hyperplastic, leading to anemia and jaundice due to effects of hemolysis. Often associated with vaso-occlusive crisis.

**Hypoplastic/aplastic crisis:** May be secondary to severe (usually viral) infection or folic acid deficiency, resulting in cessation of production of RBCs and bone marrow.

**Icterus (jaundice):** Yellowing of the skin and the whites of the eyes caused by an accumulation of bile pigment in the blood.

**Priapism:** Abnormal, painful, sustained erection of the penis, usually occurring without sexual desire. Can last for hours or days.

**Pulmonary hypertension:** Increased pressure in the pulmonary arteries that carry blood from the heart to the lungs to pick up oxygen.

**Reticulocytes:** Immature RBCs, typically composing about 1% of the red cells in the human body. Reticulocytes develop and mature in the red bone marrow and then circulate for about a day in the bloodstream before developing into mature RBCs.

**Sickle cell disease (SCD):** A person is born with SCD, an inherited disorder of the RBCs where the individual inherits two genes for hemoglobin S, or a single S gene is combined with a second variant gene such as C or Thal.

**Sickle cell trait:** A person who has sickle cell trait is a carrier of the sickle gene but does not have the disease or incur painful episodes and is generally not affected by the sickle hemoglobin. The gene combination for sickle trait is one gene for the usual hemoglobin (A) and one gene for sickle hemoglobin. *Note:* People with SCT can have children born with sickle cell disease.

**Splenic sequestration crisis:** Occurs when the spleen suddenly traps large numbers of RBCs, causing splenomegaly, a drop in hemoglobin greater than or equal to 20%, hypovolemia, shock, and possible death.

**Thalassemia (Thal):** An inherited disorder of the gene in the RBCs, which results in the impaired ability to produce hemoglobin.

**Vaso-occlusive/sickle cell crisis:** Related to infection, dehydration, fever, hypoxia, and characterized by multiple infarcts of bones, joints, and target organs, with tissue pain and necrosis caused by plugs of sickled cells in the microcirculation.

## CARE SETTING

Sickle cell disease is generally managed at the community level, with many of the interventions included here being appropriate for this focus; however, this plan of care addresses sickle cell crisis, which usually requires hospitalization during the acute phase to address oxygenation and severe pain.

## CLIENT ASSESSMENT DATABASE

\*\*\*\*Depends on severity of condition and presence of complications.

### DIAGNOSTIC DIVISION MAY REPORT

#### ACTIVITY/REST

- Lethargy, fatigue, weakness, general malaise
- Decreased exercise tolerance, impaired mobility

### MAY EXHIBIT

- Listlessness, severe weakness, and increasing pallor (aplastic crisis)

**MAY REPORT (continued)**

- Greater need for sleep and rest

**CIRCULATION**

- Palpitations or anginal chest pain due to concomitant coronary artery disease (CAD), myocardial ischemia, or acute chest syndrome (ACS)
- **P** Puffy, tender hands and feet, refusal to bear weight, irritability in children less than 2 years of age (Pack-Mabien, 2009)

**ELIMINATION**

- Frequent voiding, voiding in large amounts
- Nocturia

**EGO INTEGRITY**

- Negative feelings about self, ability to deal with life or situation
- Resentment and frustration with disease, fear of rejection from others
- Concern regarding being a burden to significant others (SOs), financial concerns, possible loss of insurance benefits, lost time at work or school, fear of genetic transmission of disease

**FOOD/FLUID**

- Anorexia
- Nausea, vomiting
- Thirst

**HYGIENE**

- Difficulty maintaining activities of daily living (ADLs) (pain or severe anemia)

**MAY EXHIBIT (continued)**

- Gait disturbances (pain, kyphosis, lordosis), inability to walk (pain)
- Decreased range of motion (ROM)
- Joint, bone deformities
- Generalized retarded growth, tower-shaped skull with frontal bossing, disproportionately long arms and legs, short trunk, narrowed shoulders and hips, and long, tapered fingers

- Apical pulse—point of maximal impulse (PMI) may be displaced to the left
- Tachycardia, S-T elevation
- Systolic heart murmurs may be heard over entire precordium
- **P** Hypertension or abnormal blood pressure patterns (elevations and dips) in children (Maakaron & Taher, 2017)
- Blood pressure (BP)—widened pulse pressure
- Capillary refill delayed (anemia or hypovolemia)
- Generalized symptoms of shock—hypotension; rapid, thready pulse; and shallow respirations during sequestration crisis
- Peripheral pulses throbbing on palpation
- Bruits—reflects compensatory mechanisms of anemia; may also be auscultated over the spleen because of multiple splenic infarcts
- Jugular vein distention (JVD) and general peripheral edema (concomitant heart failure [HF])
- **Skin color:** Pallor or cyanosis of skin, mucous membranes, and conjunctiva (*Note:* Pallor may appear as yellowish- brown color in brown-skinned clients and as ashen gray in black-skinned clients.)
- Scleral icterus, generalized icteric coloring due to excessive RBC hemolysis

- Right upper quadrant (RUQ) abdominal tenderness, enlargement due to hepatomegaly or ascites
- Left upper quadrant (LUQ) abdominal fullness; spleen may be enlarged and nonfunctional and may eventually become fibrotic and shrunken.
- Dilute, pale, straw-colored urine; hematuria or smoky appearance from multiple renal infarcts
- Asymptomatic proteinuria
- Anxiety, restlessness, irritability, apprehension, withdrawal, narrowed focus, self-focusing, unresponsiveness to questions, regression, depression, decreased self-concept
- Dependent relationship with whomever can offer security and protection

- **P** Child's height and weight usually in the lower percentiles (Maakaron & Taher, 2017)
- Dry skin and mucous membranes
- Poor skin turgor with visible tenting during sequestration crisis, infection, and dehydration

- Unkempt appearance, poor personal hygiene

(continues on page 556)

**NEUROSENSORY**

- Headaches or dizziness
- Disturbances in pain and position sense
- Visual disturbances due to retinal vascular changes

- Mental status usually unaffected except in cases of severe sickling (cerebral infarction and intracranial hemorrhage)
- Meningeal irritation (intracranial hemorrhage)—decreasing level of consciousness (LOC), nuchal rigidity, focal neurological deficits, vomiting, severe headache
- Weakness of the mouth, tongue, and facial muscles; aphasia (in cerebral infarction of dominant hemisphere)
- Abnormal reflexes, decreased muscle strength and tone, abnormal involuntary movements, hemiplegia or sudden hemiparesis, quadriplegia
- Ataxia, seizures

**PAIN/DISCOMFORT**

- Pain includes three types: acute recurrent painful crises, chronic pain syndromes, and neuropathic pain.
- Pain onset is sudden and may be acute and severe, throbbing, of varied locations (two or more sites). (The acute painful crisis is the most common cause of hospitalization [Ballas et al, 2012].)
- Pain may be localized or migratory and most commonly involves the lower back, in one or more joints or extremities.
- Joint or bone pain may be low level and chronic or acute and accompanied by warmth, tenderness, erythema, and occasional effusions (vaso-occlusive crisis).
- Intermittent pain in legs when walking
- Bone pain in long bones of extremities (bone marrow infarction) (Maakaron & Taher, 2017)
- Recurrent, sharp, transient headaches
- Abdominal tenderness and pain

- Sensitivity to palpation over affected areas
- Guarding or holding joints in position of comfort, decreased ROM, resulting from joint pain and swelling
- Maladaptive pain behaviors—guilt for being ill, denial of any aspect of disease, indulgence in precipitating factors such as overwork, strenuous exercise

**RESPIRATION**

- Dyspnea on exertion or at rest
- History of repeated pulmonary infections, infarctions, pulmonary fibrosis, pulmonary hypertension, or cor pulmonale

- Acute respiratory distress—dyspnea, chest pain, and cyanosis (especially in crisis)
- **P** Cough with fever (in children with acute chest syndrome; not always present in adults) (Vacca & Blank, 2017)
- Bronchial or bronchovesicular sounds in lung periphery, diminished breath sounds (pulmonary fibrosis)
- Crackles, rhonchi, wheezes, diminished breath sounds (HF)
- Increased anteroposterior (AP) diameter of the chest (barrel chest)

**SAFETY**

- History of repeated, frequent blood transfusions
- Jaundice with skin itching
- Impaired vision (sickle retinopathy), decreased visual acuity (temporary or permanent blindness)

- Leg ulcers—especially common on the internal and external malleoli and the medial aspect of the tibia

**SEXUALITY**

- Loss of libido
- Amenorrhea
- Complications of pregnancy, including placenta previa and abruption; premature birth or fetal death
- Priapism, impotence

- Delayed sexual maturity
- Pale cervix and vaginal walls (anemia)

**TEACHING/LEARNING**

- Chronic anemic state

**MAY REPORT (continued)**

- Pulmonary hypertension or cor pulmonale (multiple pulmonary infections and infarctions)
- Chronic leg ulcers, delayed healing

**MAY EXHIBIT (continued)****DISCHARGE PLAN CONSIDERATIONS**

- May need assistance with shopping, transportation, self-care, homemaker and maintenance tasks

► Refer to section at end of plan for postdischarge considerations.

**DIAGNOSTIC STUDIES**

TEST	WHY IT IS DONE	WHAT IT TELLS ME
<p><b>BLOOD TESTS</b></p> <ul style="list-style-type: none"> <li>• <b>Complete blood count (CBC):</b> Battery of screening tests, which typically includes Hgb; hematocrit (Hct); RBC count, morphology, indices, and distribution width index; platelet count and size; and white blood cell (WBC) count and differential.</li> <li>• <b>Red blood cells</b> <ul style="list-style-type: none"> <li>• <b>Reticulocyte count:</b> Measures how fast red blood cells are made by the bone marrow and released into the blood.</li> </ul> </li> <li>• <b>Stained RBC (erythrocyte) examination:</b> Evaluates changes in morphology of RBCs.</li> <li>• <b>High-performance liquid chromatography (HPLC):</b> Separates different forms of proteins in a column and can detect mutant forms of hemoglobin.</li> <li>• <b>Sickle-turbidity tube test (Sickledex):</b> Detects the presence of hemoglobin S in blood.</li> <li>• <b>Alkaline phosphatase (ALP):</b> Enzyme found primarily in the liver.</li> <li>• <b>Lactate dehydrogenase (LDH):</b> Indicator of the existence and severity of acute or chronic tissue damage.</li> </ul>	<p>Hgb and total RBCs are decreased. Young WBCs (leukocytes) are elevated, especially in vaso-occlusive crisis. Platelets are often increased. <i>Note:</i> Anemia is often well tolerated by the client; however, a major drop in Hgb from previously recorded values indicates a hematologic crisis. If the reticulocyte count is normal, splenic sequestration is the probable cause. If the reticulocyte count is low, an aplastic crisis is the probable cause.</p> <p>Young RBCs (reticulocytes) can be low or elevated if anemia is longstanding. If the reticulocyte count is normal, splenic sequestration is the probable cause. If the reticulocyte count is low, an aplastic crisis is the probable cause. <i>Note:</i> The life span of an RBC is normally 90 to 120 days, while the life of a sickle cell is 10 to 20 days, indicating how fragile sickle cells are and how rapidly they are destroyed as they circulate (Vacca &amp; Blank, 2017).</p> <p>Demonstrates partially or completely sickled, crescent-shaped cells, Howell-Jolly bodies, basophilic stippling, and occasional nucleated RBCs (normoblasts).</p> <p>This technique differentiates between usual hemoglobin (A), sickle hemoglobin (S), and many other different kinds of hemoglobin. In sickle cell <i>trait</i>, more than half of the hemoglobin is normal (hemoglobin A) and less than half is abnormal (hemoglobin S). In sickle cell <i>disease</i>, almost all hemoglobin is hemoglobin S with some hemoglobin called hemoglobin F (Thompson &amp; Steinberg, 2015). <b>P</b> <i>Note:</i> Screening tests for SCD are performed routinely on newborns in most states. Prenatal diagnosis is possible by molecular genetic testing if the beta-globin-related hemoglobinopathies (HBB) pathogenic variants have been identified in the parents.</p> <p>Positive if 10% of hemoglobin S is present but does not differentiate between sickle cell anemia and sickle cell trait.</p> <p>Elevated during vaso-occlusive crisis, reflecting bone and liver damage.</p> <p>Elevated because of RBC hemolysis.</p>	<p>(continues on page 558)</p>

## DIAGNOSTIC STUDIES (contd.)

WHY IT IS DONE (continued)	WHAT IT TELLS ME (continued)
<ul style="list-style-type: none"><li><b>Serum iron:</b> Iron balance is not easily achieved in sickle cell disease.</li></ul>	Deficiency is associated with premature destruction of young RBCs. However, the iron stores released by hemolysis may be available for reuse; therefore, serum iron deficiency is not always present. <b>P</b> A very high iron level is associated with frequent blood transfusions for sickle cell anemia—a condition more common in children than adults.

## OTHER DIAGNOSTIC STUDIES

- Bone x-rays and scans:** Evaluate skeletal changes.
- Chest x-ray:** Performed to check for pulmonary infiltrate.
- Magnetic resonance imaging (MRI):** An imaging test that uses magnets and radio waves to create pictures of the body.
- Transcranial Doppler (TCD) studies:** A noninvasive ultrasound technology for imaging blood flow in the cerebral arteries and veins.
- Echocardiography**
- Urine/fecal urobilinogen:** Substance formed in the intestine from the breakdown of bilirubin; some is excreted in feces and some is reabsorbed and excreted in bile or urine.
- Abdominal/pelvic ultrasound:** Performed to evaluate condition of organs.

May demonstrate bone infarction, osteomyelitis, avascular necrosis of hip, and so forth. *Note:* In the spine, “H-shaped deformity” of the vertebrae is common (formerly termed “Lincoln Log” appearance) (Ramirez & Asrat, 2017).

May confirm presence of acute chest syndrome if a new consolidation or infiltrate is accompanied by other symptoms such as chest pain, elevated temperature, or hypoxemia (Field & DeBaun, 2017; Heeney & Mahoney, 2015).

The definitive test to rule out cerebral infarct. Also identifies bone marrow changes due to acute and chronic bone marrow infarction, marrow hyperplasia, osteomyelitis, and osteonecrosis (Maakaron & Taher, 2017).

Detects large vessel disease that is often involved in overt cerebral vascular accidents in patients with SCD (Meier & Miller, 2012). **P** *Note:* The Stroke Prevention Trial in Sickle Cell Anemia (STOP) demonstrated the value of TCD screening for children with SCD at high risk for ischemic cerebral injury, including stroke (Naffaa et al., 2015).

Can identify pulmonary hypertension or cardiac involvement associated with anemia (e.g., enlarged heart).

These sensitive indicators of RBC destruction are increased.

Documents spleen size and presence of biliary or kidney stones.

## NURSING PRIORITIES

- Promote adequate cellular oxygenation and perfusion.
- Alleviate pain.
- Prevent complications.
- Provide information about disease process, prognosis, and treatment needs.

## DISCHARGE GOALS

- Oxygenation and perfusion are adequate to meet cellular needs.
- Pain relieved or controlled.
- Complications prevented or minimized.
- Disease process, future expectations, potential complications, and therapeutic regimen understood.
- Plan in place to meet needs after discharge.

## NURSING DIAGNOSIS: **impaired Gas Exchange**

### May Be Related To

Altered blood flow [altered oxygen-carrying capacity of the blood, reduced RBC life span or premature destruction, abnormal RBC structure, sensitivity to low-oxygen occlusions created by sickled cells packing together within the capillaries]

### Possibly Evidenced By

Abnormal breathing pattern; dyspnea, use of accessory muscles  
Cyanosis (hypoxia)  
Restlessness, confusion, somnolence; fatigue  
Tachycardia

**NURSING DIAGNOSIS: impaired Gas Exchange (continued)****Desired Outcomes/Evaluation Criteria—Client Will****Respiratory Status: Gas Exchange NOC**

Demonstrate improved ventilation and oxygenation as evidenced by respiratory rate within normal limits, absence of cyanosis, use of accessory muscles, and clear breath sounds.

Participate in ADLs without weakness and fatigue.

Display improved or normal pulmonary function tests.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Respiratory Monitoring NIC</b>	
<i>Independent</i>	
Monitor respiratory rate and depth, use of accessory muscles, and areas of cyanosis.	Indicators of adequacy of respiratory function or degree of compromise and therapy needs and effectiveness.
Auscultate breath sounds, noting presence or absence, and adventitious sounds.	Development of atelectasis and stasis of secretions can impair gas exchange.
Monitor vital signs; note changes in cardiac rhythm.	Changes in vital signs and development of dysrhythmias reflect effects of hypoxia on cardiovascular system.
Investigate reports of chest pain and increasing fatigue. Observe for signs of increased fever, cough, and adventitious breath sounds.	Reflective of developing acute chest syndrome, which increases the workload of the heart and oxygen demand.
Assess LOC and mentation regularly.	Brain tissue is very sensitive to decreases in oxygen, and changes in mentation may be an early indicator of developing hypoxia.
<b>Ventilation Assistance</b>	
<i>Assist</i>	
Assist in turning, coughing, and deep-breathing exercises.	Promotes optimal chest expansion, mobilization of secretions, and aeration of all lung fields; reduces risk of stasis of secretions and pneumonia.
Evaluate activity tolerance; limit activities to those within client's tolerance or place client on bedrest. Assist with ADLs and mobility, as needed.	Reduction of the metabolic requirements of the body reduces the oxygen requirements and degree of hypoxia.
Encourage client to alternate periods of rest and activity. Schedule rest periods, as indicated.	Protects from excessive fatigue and reduces oxygen demands and degree of hypoxia.
Demonstrate and encourage use of relaxation techniques, such as guided imagery and visualization.	Relaxation decreases muscle tension and anxiety and, hence, the metabolic demand for oxygen.
Promote extra fluid intake, such as 2 to 3 L/d within cardiac tolerance.	Sufficient hydration is necessary to provide for mobilization of secretions and to prevent hyperviscosity of blood with associated capillary occlusion.
Screen health status of visitors and staff.	Protects client from potential sources of respiratory infection.
<i>Collaborative</i>	
Administer supplemental humidified oxygen, as indicated.	Maximizes oxygen transport to tissues, particularly in the presence of pulmonary insults or pneumonia. Note: Oxygen should be given only in the presence of confirmed hypoxemia because oxygen can suppress erythropoietin levels, further reducing the production of RBCs.
Monitor laboratory studies—CBC (especially noting Hgb and WBCs), blood cultures, arterial blood gases (ABGs) and pulse oximetry, chest x-ray, and pulmonary function tests (when available).	Client is particularly prone to acute chest syndrome and pneumonia (which is potentially fatal because of its hypoxic effect of increased sickling). Note: Most individuals with sickle cell anemia have hemoglobin (Hgb) values of 6 to 10 g/dL. The hemoglobin S molecule has a low affinity for oxygen (which allows for adequate tissue oxygenation). During a vaso-occlusive crisis, a client's Hgb level often declines by at least 1 g/dL.
Perform or assist with chest physiotherapy, intermittent positive-pressure breathing (IPPB), and incentive spirometry.	Mobilizes secretions and increases aeration of lung fields.

(continues on page 560)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Administer packed RBCs (PRCs) or exchange transfusions, as indicated.	Simple blood transfusion increases the number of oxygen-carrying cells, dilutes the percentage of hemoglobin S, and improves circulation. PRCs are used because they are less likely to create circulatory overload. Exchange blood transfusions are indicated when the client's condition is deteriorating and may be done for cases of stroke (Kassim et al, 2015) and acute chest syndrome. Note: Studies have shown that blood transfusion therapy for patients with SCD and abnormal TCD velocities can dramatically reduce risk of stroke (Yates, 2017). Partial transfusions are sometimes used prophylactically in high-risk situations, such as chronic, severe leg ulcers, preparation for general anesthesia, and third trimester of pregnancy.
Administer medications, as indicated, for example:  Antibiotics, such as amoxicillin plus clavulanic acid (Augmentin), third-generation cephalosporins (e.g., ceftriaxone [Rocephin]), among others	Broad-spectrum antibiotics are started immediately pending culture results of suspected infections, then may be changed when the specific pathogen is identified.  <b>P</b> Because infection is one of the most common causes of ACS in children and adolescents, broad-spectrum antibiotic coverage has been recommended for all children presenting with ACS (Heeney & Mahoney, 2015).

### NURSING DIAGNOSIS: acute/chronic Pain

#### May Be Related To

Biological injury agent (e.g., intravascular sickling with localized stasis, occlusion, infarction, and necrosis; activation of pain fibers due to deprivation of oxygen and nutrients, accumulation of noxious metabolites)

#### Possibly Evidenced By

Self-report of intensity and characteristics of pain, using standardized pain scale; proxy report of pain behavior and activity changes (e.g., family member, care provider)

Guarding and protective behaviors

Facial grimacing, narrowed or self-focus; sleep disturbances

Changes in physiological parameter in acute pain (e.g., blood pressure, heart and respiratory rate)

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Pain Level NOC

Verbalize relief or control of pain.

##### Pain Control NOC

Demonstrate relaxed body posture, freedom of movement, and ability to sleep and rest appropriately.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Pain Management: Acute /Chronic NIC</b> <i>Independent</i> Assess reports of pain, including location, duration, and intensity (0 to 10 or similar coded scale). Have client help differentiate current pain from typical or usual pain problems.	Acute pain in patients with sickle cell disease can be localized, migratory, or more generalized and described as throbbing, gnawing, or severe and incapacitating. Pain is caused by ischemic tissue injury resulting from the occlusion of microvascular beds by sickled erythrocytes during an acute crisis. Typically, acute pain occurs deep in the bones and muscles of back, ribs, and limbs and lasts 5 to 7 days. However, client may also have chronic pain from previous sickle cell damage (usually bone pain that is present daily) and chronic nerve pain caused by damage from sickle cell blockage or other conditions, such as diabetes.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Observe nonverbal pain cues, such as gait disturbances, body positioning, reluctance to move, and facial expressions, and physiological manifestations of acute pain—elevated BP, tachycardia, and increased respiratory rate. Explore discrepancies between verbal and nonverbal cues.	Nonverbal cues may aid in evaluation of pain and effectiveness of therapy. Pain is unique to each client; therefore, one may encounter varying descriptions because of individualized perceptions. <b>P</b> Note: Evaluating pain in infants, children, and adolescents is not as simple as using a coded scale. Attention must be paid to caregivers' reports and child's behavior (e.g., inconsolable crying, changes in crying patterns, curling up in a fetal position, changes in sleep patterns; going silent; withdrawing from touch, refusing eye contact).
Discuss with the client/SO what pain relief measures were effective in the past.	Involves client/SO in care and allows for identification of remedies that have already been found to relieve pain. Helpful in establishing individualized treatment needs.
Explore alternative pain relief measures, such as relaxation techniques, biofeedback, yoga, meditation, and distraction—visual, auditory, tactile, kinesthetic, guided imagery, and breathing techniques.	Cognitive-behavioral interventions may reduce reliance on pharmacological therapy and enhance client's sense of control, especially when dealing with chronic pain.
Provide support for and carefully position affected extremities.	Reduces edema, discomfort, and risk of injury, especially if osteomyelitis is present.
Apply local massage gently to affected areas.	Helps reduce muscle tension.
Plan activities during peak analgesic effect.	Maximizes movement of joints, enhancing mobility.
Maintain adequate fluid intake.	Dehydration increases sickling vaso-occlusion and corresponding pain.
<b>Collaborative</b>	
Apply warm, moist compresses to affected joints or other painful areas. Avoid use of ice or cold compresses.	Warmth causes vasodilation and increases circulation to hypoxic areas. Cold causes vasoconstriction and compounds the crisis.
Administer medications by appropriate route (such as continuous infusion or around-the-clock intermittent IV or oral, as indicated), for example:	Various types of analgesics are needed to manage different types of pain.
Opioids including morphine (Astramorph, Duramorph), hydromorphone (Dilaudid), and nalbuphine (Nubain); long-acting opiate combinations, such as morphine (MS Contin) and oxycodone (Oxycontin), hydrocodone (Vicodin); oxycodone and acetaminophen (Percocet)	Opioids are the mainstay of pain control during crisis and are usually administered via patient-controlled analgesia (PCA). Oral preparations are preferred for longer-term treatment and can be initiated while client is still on IV analgesia. Note: Meperidine should not be used to treat acute sickle cell pain in client with impaired renal function, history of seizure disorder, or those on serotonergic medications (e.g., certain antidepressants and combination drugs containing serotonin-norepinephrine reuptake inhibitors).
Nonopioid analgesics, such as acetaminophen (Tylenol); nonsteroidal anti-inflammatory drugs (NSAIDs), such as ibuprofen (Advil, Motrin); Ketrolac	Acetaminophen and NSAIDs add to the effects of opioids during painful crisis. Acetaminophen can be used for control of headache, pain, and fever. <b>P</b> Ketrolac (a nonsedating analgesic) may be used in children to relieve spine, thoracic, and abdominal pain (often accompanies hypoventilation in acute chest syndrome) (Heeney & Mahoney, 2015). Note: Aspirin should be avoided because it alters blood pH and can make cells sickle more easily.
Consult with or refer to physical therapy.	Determines and provides appropriate therapies, such as massage, heat therapies, and guided exercise.
Administer and monitor RBC transfusion.	Although transfusion does not halt the pain in an acute crisis, frequency of painful crises may be reduced by regular partial exchange transfusions to maintain population of normal RBCs.

**NURSING DIAGNOSIS:** **risk for ineffective Tissue Perfusion [specify: cardiac, cerebral, gastrointestinal, peripheral]**

**Possibly Evidenced By**

Coagulopathy (e.g., vaso-occlusive nature of sickling, inflammatory response)  
Hypovolemia; hypoxemia  
Deficient knowledge of aggravating factors

**Desired Outcomes/Evaluation Criteria—Client Will**

**Tissue Perfusion NOC**

Demonstrate improved tissue perfusion as evidenced by stabilized vital signs, strong and palpable peripheral pulses, adequate urine output, absence of pain; usual mentation; normal capillary refill; skin warm and dry; nailbeds and lips of natural pale, pink color; and absence of paresthesias.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Circulatory Care: Arterial [or] Venous</b>	
<b>Insufficiency NIC</b>	
<i>Independent</i>	
<b>Impaired systemic and cardiovascular perfusion</b>	
Monitor vital signs carefully. Assess pulses for rate, rhythm, and volume. Note changes in blood pressure.	Sludging and sickling in peripheral vessels may lead to complete or partial obliteration of a vessel with diminished perfusion to surrounding tissues.
Assess heart sounds and pulses for dysrhythmias.	May reflect problems with cardiac output (systemic dehydration and/or hypoxemia), electrolyte imbalances, or local or systemic sickling causing inadequate myocardial perfusion.
Assess for restlessness, changes in level of consciousness, increased capillary refill time, diminished peripheral pulses, and pale, cool skin.	Indicative of inadequate systemic perfusion.
Note onset of hypotension with rapid, weak, thready pulse and tachypnea with shallow respirations.	Sudden massive splenic sequestration of cells can lead to systemic shock.
Investigate reports of chest pain.	To evaluate for potential myocardial ischemia, inadequate systemic oxygenation, or perfusion of organs.
<b>Impaired general and peripheral perfusion</b>	
Assess extremities for skin texture, edema, and ulcerations, especially of internal and external ankles.	Edema may reflect both systemic and peripheral effects of sickle cell disease. Reduced peripheral circulation often results in skin and underlying tissue changes (e.g., ulcerations) and delayed healing.
Investigate reports of eye pain or vision disturbances.	Changes may reflect occlusion of vasculature and nerves of the eye.
<b>P Evaluate for developing edema—including hands and feet in children and genitalia in boys and men.</b>	Vaso-occlusion or circulatory stasis may lead to edema of extremities and priapism, potentiating risk of tissue ischemia and necrosis. <b>P Note:</b> Edematous hands and feet are often first sign of SCD in young children.
Maintain comfortable environmental temperature and body warmth without overheating. Avoid hypothermia.	Prevents vasoconstriction, aids in maintaining circulation and perfusion. Excessive body heat may cause diaphoresis, adding to insensible fluid losses and risk of dehydration. Hypothermia may exacerbate cardiovascular compromise with severe anemia.
Monitor urine output.	Decreased output may be indicative of dehydration, impaired cardiac output, or impaired renal perfusion because of vascular occlusions. (Refer to ND: risk for deficient Fluid Volume, following; and CP: Renal Failure/Acute/Chronic.)
<b>Risk for impaired respiratory system perfusion</b>	
Monitor respirations, noting rate outside of acceptable parameters and drop in pulse oximetry. Note client reports of/demonstration of difficult breathing.	May indicate presence of oxygen exchange problems, presence of respiratory infection, or acute chest syndrome.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Assess skin for coolness, pallor, cyanosis, and diaphoresis.	Changes reflect diminished circulation and hypoxia potentiating capillary occlusion. (Refer to ND: Impaired Gas Exchange.)
<b>Risk for ineffective cerebral perfusion</b> Note changes in level of consciousness and mentation; reports of headaches, dizziness; development of sensory or motor deficits, such as hemiparesis or paralysis; and seizure activity.	Changes may reflect diminished perfusion to the brain and central nervous system (CNS) due to ischemia or infarction (stroke). <b>P</b> Note: Researchers have demonstrated that the scenario of high blood pressure and anemia occurring together places children with SCD at serious danger for symptomless or so-called silent stroke, which causes subclinical brain damage (Wolf et al, 2015). (Refer to CP: Cerebral Vascular Accident/Stroke, if indicated.)
<b>Ineffective Gastrointestinal Perfusion</b> Auscultate abdomen to evaluate for peristaltic activity, especially in the presence of vomiting and abdominal pain.	May indicate presence of bowel ischemia or obstruction, or other abdominal pathology, such as cholecystitis ( <b>P</b> especially common in children) (Maakaron & Taher, 2017).
Note increasing abdominal girth, especially when accompanied by general deterioration in clinical status (i.e., sudden weakness, pale lips, rapid breathing, excessive thirst, belly pain, and rapid heartbeat) and severe anemia.	May indicate presence of splenic sequestration (occurs when large numbers of sickled red blood cells become trapped in the spleen, causing it to suddenly enlarge). <b>P</b> This condition is more common in infants and young children. Without emergency medical care, splenic sequestration can cause death in a matter of hours (Thompson, 2015).
<b>Collaborative</b> Monitor laboratory studies, such as the following:	
Arterial blood gases (ABGs), liver and kidney function tests	Decreased tissue perfusion may lead to gradual infarction of organ tissues, such as the brain, liver, spleen, kidney, and skeletal muscle, with consequent multiorgan failure.
Serum electrolytes; provide replacements as indicated.	Electrolyte losses, especially sodium and potassium, are increased during crisis because of fever, diarrhea, vomiting, diaphoresis, and presence of acidosis.
Administer oxygen by appropriate route and assist with respiratory treatment measures, such as coughing, deep-breathing exercises, and incentive spirometer.	Improves oxygenation and reduces risk of pulmonary complications. (Refer to ND: Impaired Gas Exchange, above.)
Administer intravenous (IV) solutions, such as 0.45 normal saline, via an infusion pump.	Hydration lowers the hemoglobin S concentration, which decreases the sickling tendency and also reduces blood viscosity, which helps to maintain perfusion. Infusion pump may prevent circulatory overload. Note: Lactated Ringer's solution or D <sub>5</sub> W may cause RBC hemolysis and potentiate thrombus formation.
Administer hydroxyurea (hydroxycarbamide [Droxia, Hydrea]) and observe for possible side effects.	Hydroxyurea, a cytotoxic agent, reduces or prevents many complications of SCD by increasing the circulation of normal or fetal hemoglobin (HbF). It dramatically decreases the number of VOC episodes and the need for transfusions and hospitalizations and is given to prevent crises. Note: Hydroxyurea is not used in the acute setting, as it takes weeks to months to be effective, and thus is used to treat complications. <b>P</b> This drug is used across the life span, including in infants and young children, as long as renal clearance is effective (Rodgers & George, 2017; Vacca & Blank, 2017).
Administer deferoxamine (Desferal) and vitamin C.	Chelation therapy may be indicated to correct iron overload associated with regular, frequent transfusions. Vitamin C may enhance iron excretion, especially in clients who are vitamin deficient. Note: Phlebotomy and exchange transfusions may be used in conjunction with chelation therapy.
Prepare for and assist with procedures as needed (e.g., surgical intervention or needle aspiration of blood from corpora cavernosa).	Sickling within the penis can cause priapism and edema. Removal of sludged, sickled cells can improve circulation, decreasing psychological trauma and risk of necrosis and infection.

## NURSING DIAGNOSIS: risk for deficient Fluid Volume

### Possibly Evidenced By

Factors influencing fluid needs (e.g., hypermetabolic state or fever, inflammatory or vaso-occlusive processes; deviations affecting intake or absorption)  
Active fluid loss (compromised regulatory function; renal parenchymal damage or infarctions limiting the kidney's ability to concentrate urine)

### Desired Outcomes/Evaluation Criteria—Client Will

#### Hydration NOC

Maintain adequate fluid balance as evidenced by individually appropriate urine output with a near-normal specific gravity, stable vital signs, moist mucous membranes, good skin turgor, and prompt capillary refill.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Fluid Monitoring NIC</b> <i>Independent</i> Maintain accurate intake and output (I&O). Weigh daily.	Client may reduce fluid intake during periods of crisis because of malaise and anorexia. Dehydration from vomiting, diarrhea, and fever may reduce urine output and precipitate a vaso-occlusive crisis.
Note urine characteristics and specific gravity.	The kidney can lose its ability to concentrate urine, resulting in excessive losses of dilute urine and fixation of the specific gravity.
Monitor vital signs, comparing with client's usual or previous readings. Take BP in lying, sitting, and standing positions, if possible.	Reduction of circulating blood volume can occur from increased fluid loss, resulting in hypotension and tachycardia.
Observe for fever, changes in level of consciousness, poor skin turgor, dryness of skin and mucous membranes, and pain.	Symptoms are reflective of dehydration and hemoconcentration with consequent vaso-occlusive state.
Monitor vital signs closely during blood transfusions and note presence of dyspnea, crackles, rhonchi, wheezes, diminished breath sounds, cough, frothy sputum, and cyanosis.	Client's heart may already be weakened and prone to failure because of chronic demands placed on it by the anemic state. Heart may be unable to tolerate the added fluid volume from transfusions or rapid IV fluid administered to treat crisis or shock.
<b>Collaborative</b> Administer IV fluids, as indicated.	Replaces fluid deficits; may reverse renal concentration of RBCs and reduce potential for kidney failure.
Monitor laboratory studies, for example: Hgb/Hct	Elevations may indicate hemoconcentration. Posttransfusion Hgb level of 8 to 9 g/dL is generally recommended to avoid the risk of hyperviscosity that may occur several days after transfusion when RBCs sequestered in the spleen may return to the circulation and increase the Hgb levels.
Serum and urine electrolytes	Kidneys' loss of ability to concentrate urine may result in serum depletions of $\text{Na}^+$ , $\text{K}^-$ , and $\text{Cl}^-$ , necessitating replacement.

## NURSING DIAGNOSIS: impaired physical Mobility

### May Be Related To

Activity intolerance; decreased endurance  
Pain/discomfort; joint stiffness; loss of integrity of bone structures (osteoporosis, osteomyelitis)  
Prescribed movement restrictions (bedrest)

### Possibly Evidenced By

Limited joint ROM, reluctance to initiate movement; slowed movement, gait changes  
Generalized weakness

**NURSING DIAGNOSIS: impaired physical Mobility (continued)****Desired Outcomes/Evaluation Criteria—Client Will****Mobility NOC**

Maintain or increase strength and function of affected body parts.

Participate in activities with absence of or improvement in gait disturbances, increased joint ROM, and absence of inflammatory signs.

\*\*\*\*Refer to CP: Extended/Long Term Care; ND: impaired physical Mobility for appropriate actions and interventions.

**NURSING DIAGNOSIS: risk for impaired Skin Integrity****Possibly Evidenced By**

Impaired circulation (venous stasis and vaso-occlusion); impaired sensation

Mechanical factors—pressure; alteration in skin turgor

Alteration in fluid volume [including presence of edema]

**Desired Outcomes/Evaluation Criteria—Client Will****Tissue Integrity: Skin and Mucous Membranes NOC**

Prevent dermal ischemic injury.

Display improvement in wound or lesion healing if present.

**Risk Control NOC**

Participate in behaviors to reduce risk factors and skin breakdown.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Skin Surveillance NIC</b>	
<i>Independent</i>	
Reposition frequently, even when sitting in chair.	Prevents prolonged tissue pressure where circulation is already compromised, reducing risk of tissue trauma and ischemia.
Inspect skin pressure points regularly for pallor or redness and provide gentle massage.	Poor circulation may predispose to rapid skin breakdown.
Protect bony prominences with sheepskin, heel and elbow protectors, or pillows, as indicated.	Decreases pressure on tissues, preventing skin breakdown.
Keep skin surfaces dry and clean and linens dry and wrinkle-free.	Moist, contaminated areas provide excellent media for growth of pathogenic organisms.
Monitor ischemic areas, leg bruises, cuts, and bumps closely for ulcer formation.	Potential entry sites for pathogenic organisms. In presence of altered immune system, this increases risk of infection and delayed healing.
Elevate lower extremities when sitting.	Enhances venous return, reducing venous stasis and edema formation.
<i>Collaborative</i>	
Provide egg-crate, alternating air pressure, or water mattress.	Reduces tissue pressure and aids in maximizing cellular perfusion to prevent dermal injury.
Provide wound care as indicated, such as cleansing and debriding open wounds and ulcers according to protocol.	Improvement or delayed healing reflects status of tissue perfusion and effectiveness of interventions. Note: These clients are at increased risk of serious complications because of lowered resistance to infection and decreased nutrients for healing.

## NURSING DIAGNOSIS: risk for Infection

### Possibly Evidenced By

Chronic illness; malnutrition; [extremes of age]  
Alteration in skin integrity, tissue destruction (e.g., tissue and bone marrow infarction, necrosis and increased gut permeability, liver fibrosis, loss of spleen [autosplenectomy]); stasis of body fluids, decrease in ciliary action  
Decrease in hemoglobin; inadequate vaccination; immunosuppression [increased environmental exposure]

### Desired Outcomes/Evaluation Criteria—Client Will

#### Risk Control: Infectious Process NOC

Be free of infection; achieve timely wound healing; be free of preventable complications.  
Verbalize understanding of individual causative or risk factors.  
Identify interventions to prevent or reduce risk of infection.

\*\*\*Refer to CPs: Pneumonia, Sepsis/Septicemia, Fractures; ND: risk for Infection for assessments and interventions related to prevention or management of infection.

## NURSING DIAGNOSIS: ineffective Health Management

### May Be Related To

Difficulty managing complex treatment regimen or navigating complex healthcare systems  
Perceived seriousness of condition, susceptibility, benefit, or barrier  
Insufficient knowledge of therapeutic regimen  
Family pattern of healthcare; decisional conflict; excessive demands; insufficient social support

### Possibly Evidenced By

Difficulty with prescribed regimen  
Failure to take action to reduce risk factors  
Ineffective choices in daily living for meeting health goals

### Desired Outcomes/Evaluation Criteria—Client Will

#### Self-Management: Chronic Disease NOC

Verbalize understanding of disease process, including symptoms of crisis and potential complications.  
Verbalize understanding of therapeutic needs.  
Initiate necessary behaviors or lifestyle changes to prevent complications.  
Participate in continued medical follow-up, genetic counseling, and family planning services.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Teaching: Disease Process NIC</b> <i>Independent</i> Review disease process and treatment needs.	Provides knowledge base from which client can make informed choices.
Review crisis precipitating factors, such as the following:  Cold environmental temperatures, failure to dress warmly when engaging in winter activities; wearing tight, restrictive clothing; stressful situations	Causes peripheral vasoconstriction, which may result in sludging of the circulation, increased sickling, and may precipitate a vaso-occlusive crisis.
Strenuous physical activity or contact-type sports and extremely warm temperatures	Increases metabolic demand for oxygen and increases insensible fluid losses (evaporation and perspiration), leading to dehydration, which may increase blood viscosity and tendency to sickle.
Travel to places more than 7000 ft above sea level or flying in unpressurized aircraft	Decreased oxygen tension present at higher altitudes causes hypoxia and potentiates sickling of cells. Note: Even though commercial airline cabins are pressurized, low cabin humidity increases risk of dehydration.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Encourage consumption of at least 3 to 4 L of fluid daily, during a steady state, increasing to 6 to 8 L (as individually tolerated, prescribed, or required) during a painful crisis or while engaging in activities that might precipitate dehydration.	Prevents dehydration and consequent hyperviscosity that can potentiate sickling and crisis.
Discuss continuation of use of prescribed medications, such as hydroxyurea (Hydrea).	Has been found to reduce frequency of pain episodes in adults.
Encourage ROM exercise and regular physical activity with a balance between rest and activity.	Prevents bone demineralization and may reduce risk of fractures. Aids in improving general health status and muscle and bone strength.
Review client's current diet, reinforcing the importance of diet including meats and dairy, green leafy vegetables, citrus fruits, and wheatgerm. Provide necessary instruction regarding supplementary vitamins such as folic acid.	Nutritious foods, including vitamins, folate, and B <sub>12</sub> in greater quantities than usual, are essential because of increased demands placed on bone marrow. Folic acid supplements are frequently ordered to prevent aplastic crisis.
Emphasize importance of avoiding smoking and alcohol consumption; identify appropriate medical assistance and community support groups for smoking cessation.	Nicotine induces peripheral vasoconstriction and decreases oxygen tension, which may contribute to cellular hypoxia and sickling. Alcohol increases the possibility of dehydration, which precipitates sickling. Maintaining these changes in behavior or lifestyle may require prolonged support.
Discuss principles of skin and extremity care and protection from injury. Encourage prompt treatment of cuts, insect bites, sores, and lesions.	Because of impaired tissue perfusion, especially in the periphery, distal extremities are especially susceptible to altered skin integrity and infection.
Include instructions on care of leg ulcers that might develop.	Fosters independence and maintenance of self-care at home.
Instruct client to avoid persons with infections such as upper respiratory infections (URIs).	Altered immune response places client at risk for infections, especially bacterial bronchitis and pneumonia.
Recommend avoiding cold remedies and decongestants containing ephedrine and large amounts of caffeine. Stress the importance of reading labels on over-the-counter (OTC) drugs and consulting healthcare provider before consuming any drugs or herbal supplements.	Those remedies containing vasoconstrictors may decrease peripheral tissue perfusion and cause sludging of sickled cells.
Discuss conditions for which medical attention should be sought, such as the following:	
Urine that appears blood tinged or smoky	Symptoms suggestive of sickling in the renal medulla.
Indigestion, persistent vomiting, diarrhea, high fever, and excessive thirst	Dehydration may trigger a vaso-occlusive crisis.
Increasingly severe joint or bone pain	May signify a vaso-occlusive crisis due to sickling in the bones or spleen, leading to ischemia or infarction or onset of osteomyelitis.
Severe chest pain, with or without cough	May reflect acute chest syndrome, with pulmonary infiltrates or pneumonia.
Abdominal pain; gastric distress following meals	Cholelithiasis, primarily with bilirubin stones, is present in more than 50% of adults.
Priapism episode persisting over 4 hours with no resolution	Suggestive of sickling in the penis.
Persistent fever greater than 100°F (38°C); increasing fatigue and pallor; dizziness, drowsiness; and nonhealing leg ulcers	Suggestive of infections that may precipitate a vaso-occlusive crisis if dehydration develops. Note: Severe infections are the most frequent cause of aplastic crisis.
Any neurological symptom or sign	Stroke can occur due to cerebral infarction, although it is more common in children than adults. Without long-term transfusion therapy, approximately one-third of clients will experience recurrent strokes.
Review and strengthen coping abilities, such as how to deal appropriately with anxiety, getting adequate information, and using relaxation techniques.	Promotes client's sense of control and may avert a crisis.

(continues on page 568)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Recommend wearing a medical alert bracelet or carrying a wallet card.	May prevent inappropriate treatment in emergency situation.
Discuss genetic implications of the condition. Encourage SO and family members to seek testing to determine presence of hemoglobin S.	Screening may identify other family members with sickle cell trait. Hereditary nature of the disease with the possibility of transmitting the mutation may have a bearing on reproductive decisions.
Explore concerns regarding childbearing and family planning.	Provides opportunity to correct misconceptions and present information necessary to make informed decisions.
Refer to community resources and obstetrician knowledgeable about sickle cell disease, as indicated.	Evidence shows that pregnant client has increased risk of infections (e.g., pneumonia and genitourinary tract infections), gestational hypertension, intrauterine growth retardation, eclampsia, preterm labor, and postpartum infections (Vichinsky, 2017).
Encourage client to have routine follow-ups, such as:	
Periodic laboratory studies, such as CBC	Monitoring may be needed long term to review status of anemia and to identify potential complications.
Biannual dental examination	Sound oral hygiene limits opportunity for bacterial invasion and sepsis.
Annual ophthalmological examination	Detects development of sickle retinopathy with either proliferative or nonproliferative ocular changes predisposing to retinal hemorrhage and increased intraocular pressure.
Immunizations	Annual influenza vaccination is essential. <b>P</b> For infants with sickle cell disease, provide a suggested schedule for well-child visits to ensure that immunizations and other aspects of routine pediatric care are followed. For children aged 1 to 3 years with hemoglobin (Hb) SS and HbS- $\beta$ -0 thalassemia, consider visits every 3 months, to be certain that parents have sufficient antibiotics for prophylaxis (when used) and to encourage compliance with SCD therapies.
Determine need for vocational and career guidance.	Sedentary career may be necessary because of decreased oxygen-carrying capacity and diminished exercise tolerance.
Encourage participation in community support groups available to clients and SO, such as the Sickle Cell Disease Association of America, March of Dimes, public health services, and visiting nurse.	Helpful in adjustment to long-term situation; reduces feelings of isolation and enhances problem-solving through sharing of common experiences. Note: Failure to resolve concerns and deal with situation may require more intensive therapy and psychological support.

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

- **acute/chronic Pain**—physical agent (e.g., intravascular sickling with localized stasis, occlusion, infarction, and necrosis; activation of pain fibers due to deprivation of oxygen and nutrients, accumulation of noxious metabolites)
- **risk for deficient Fluid Volume**—increased fluid needs (hypermetabolic state or fever, inflammatory processes), active fluid loss (renal parenchymal damage or infarctions limiting the kidney's ability to concentrate urine [hyposthenuria])
- **risk for Infection**—chronic disease; broken skin, tissue destruction, stasis of body fluids, decreased ciliary action

## ADULT LEUKEMIAS

**I. Pathophysiology**—Malignant disorders of the blood and bone marrow in which unrestrained proliferation of white blood cells occurs and is usually accompanied by anemia, impaired blood clotting, and enlargement of the lymph nodes, liver, and spleen.

- a. Blood cells originate primarily in the marrow of bones, such as the sternum, iliac crest, and cranium, and begin as immature cells (blasts or stem cells) that differentiate and mature into red blood cells (RBCs), platelets, and various types of WBCs (National Cancer Institute [NCI], 2017a).
- b. Production of normal blood cells is markedly decreased, leading to anemia, thrombocytopenia, neutropenia
- c. Rapid growth of immature or ineffective WBCs and delayed cell death lead to their accumulation in bone marrow, blood, spleen, and liver.

**II. Categories** (American Cancer Society [ACS], n.d; Hu, 2016; Seiter, 2017; Swierzowski, 2015)

- a. Leukemia is classified by how quickly it progresses. Acute leukemia is fast-growing and can overwhelm the body within weeks or months. Chronic leukemia is slow-growing and progressively worsens over time.
  - b. Leukemia is also classified according to the type of white blood cell that is multiplying—that is, lymphocytes (immune system cells), granulocytes (bacteria-destroying cells), or monocytes (macrophage-forming cells).
  - c. The leukemia designation also includes the site where the cancer develops (i.e., lymphocytes, myeloid [arising from bone marrow])
  - d. Although leukemia is among the most common childhood cancers, it most often occurs in adults (most frequently diagnosed among people aged 65–74) (NCI, 2017a).
  - e. The four types of leukemia that occur most frequently in adults are acute myelogenous leukemia (AML), acute lymphocytic leukemia (ALL), chronic myelogenous leukemia (CML), and chronic lymphocytic leukemia (CLL).
1. Acute leukemias
    - i. Acute leukemia cells begin to replicate before any immune functions have developed. These abnormalities result in loss of the body's ability to fight infections and prevent bleeding.
    - ii. Acute leukemias, in general, progress rapidly without treatment but can be kept in remission in a high percentage of individuals who undergo appropriate therapy. As a group, older clients tend to have worse treatment outcomes than younger ones (i.e., they experience greater treatment-related toxicity, lower remission rates, shorter disease-free survival times, and shorter overall survival times).
    - iii. The most common form of acute leukemias in adults (especially those 65 or older) is acute myelogenous leukemia (AML).
    - iv. AML (also known as acute myeloid leukemia, acute granulocytic leukemia, and nonlymphocytic leukemia) is a rapidly progressing cancer of blood and bone marrow, caused by damage to the DNA of developing cells in the bone marrow. It affects a group of white blood cells (called myeloid cells), which normally develop into the various types of mature blood cells (e.g., RBCs, WBCs, and platelets).

The abnormal cells are unable to function properly, and they can amass, crowding out healthy cells.

- v. Acute lymphoblastic leukemia (also called acute lymphocytic leukemia [ALL]) is a rapidly progressing cancer of blood, where abnormal blood cells (leukemia cells) accumulate in bone marrow and replace healthy functional lymphocytes with leukemia cells that can't mature properly. Typically, ALL is associated with having more B lymphocytes than T lymphocytes, which (1) allows invasion of infection and (2) prevents destruction of previously infected cells. The leukemia cells are then carried in the bloodstream to other organs and tissues, including the brain, liver, lymph nodes, and testes, where they continue to grow and divide.

### 2. Chronic leukemias

- a. Chronic leukemias develop gradually and progress more slowly than acute forms. The cells generally begin to form in bone marrow, mature partly (but not completely), and can affect white blood cells, red blood cells, and platelets. Leukemia cells survive longer than normal cells and can build up, crowding out normal cells. At some point, leukemia cells leave the bone marrow and spill into the bloodstream, where they can spread to other organs. Chronic leukemias can take a long time to cause problems but are generally harder to cure than acute leukemias.
- b. Whether the leukemia is myeloid or lymphocytic is determined by which bone marrow cells the cancer starts in.
- c. The most common form of chronic leukemia in adults is chronic lymphocytic leukemia (CLL). CLL accounts for about one-quarter of all leukemias, mainly affecting older adults with an average age of 71 at time of diagnosis (ACS, n.d.). CLL can spread to other parts of the body, including lymph nodes or other organs such as the liver and spleen, resulting in infections, anemia, and easy bleeding. CLL eventually causes the bone marrow to fail.
- d. Chronic myelogenous leukemia (CML) is a slowly progressing blood and bone marrow disease that usually occurs after middle age. CML (also called chronic myeloid leukemia) starts in certain blood-forming cells of the bone marrow and invades the blood. In CML, a genetic change takes place in an early immature type of myeloid cells that produce RBCs, platelets, and most types of WBCs, except lymphocytes. CML constitutes about 10% of all leukemias.
- e. Most people with CML (and some people with AML and ALL) have a particular genetic marker (the Philadelphia chromosome [Ph1]), which causes uncontrolled proliferation of all types of white blood cells and platelets. Another distinctive feature of CML is its invariable conversion, if untreated, to a more rapidly fulminating acute type, leading to rapid death (NCI, 2017a; Sherbenou & Drucker, 2007; Swierzowski, 2015).
- f. CML tends to occur more in middle-age and older-age persons. Studies have shown that most cases occur in older adults, with more than half occurring after age 67 (Leukemia & Lymphoma Society, 2016–2017).

(continues on page 570)

### III. Etiology

- a. Exact cause is unknown.
- b. Risk factors include the following (Seiter, 2017):
  - i. Antecedent histological disorders: diseases of the bone marrow, such as myelodysplastic syndrome (MDS)
  - ii. Environmental exposures: radiation, benzene (found in some work areas, gasoline-related industries, and cigarette smoke) (Phillips, 2012)
  - iii. Prior chemotherapy for other malignancies
  - iv. Genetics or congenital disorders: Some congenital disorders that predispose patients to AML include Down's syndrome, Fanconi's anemia, and neurofibromatosis.

### IV. Classification or Staging (Hu, 2016; NCI, 2017a)

In general, because leukemias start in the bone marrow and have often spread to other organs by the time of diagnosis, there is no traditional clinical staging but rather are described as untreated, in remission, or recurrent and are classified according to their genotypes, or their unique characteristics, in order to determine the most appropriate therapy. In recent years, researchers have discovered that cellular characteristics such as genetic makeup and numbers of specific cell types help to classify leukemia and predict its outcome.

- a. The most popular classification method for acute leukemia is the French-American-British (FAB) system. For example, according to the FAB classification, acute leukemia is divided into eight subtypes of acute myelogenous leukemia (AML) and three subtypes of acute lymphocytic leukemia (ALL) (NCI, 2017a). Acute promyelocytic leukemia (APL) is one subtype of AML that is considered a medical emergency because of its sudden onset and a significant risk of death due to hemorrhage (17%–29%) more than other leukemias (Draper, 2016).

- b. Chronic leukemia is classified by phase (i.e., chronic phase, accelerated phase, and blast phase [or “blast crisis”]) and is defined by the number of blasts (immature leukemia cells) in the blood and bone marrow. Chronic leukemia uses two different staging systems, both based on the parts of the body affected by the leukemia. For example, chronic lymphocytic leukemia (CLL) is classified by one of two cytologic staging systems, known as the Rai classification and Binet staging, respectively (NCI, 2017a; Swierzewski, 2015).

### V. Statistics

- a. Morbidity: Based on 2010 to 2014 data, the Survey, Epidemiology, and End Results program (SEER) projected that an estimated 62,130 new cases of leukemia (all types) would be diagnosed in 2017 in the United States, more often in males than females (National Cancer Institute, SEER, 2017a). Based on SEER data gleaned from 2008 to 2013, 60.6% of people diagnosed with leukemia will survive 5 years or more. Advances in the treatment of AML have resulted in substantially improved complete remission (CR) rates (ACS, 2017a).
- b. Mortality: Approximately 24,500 deaths from all leukemias were reported for 2010 (National Cancer Institute, SEER, 2017a). Estimated deaths from ALL in 2017 were 1440, and deaths from AML in the same period were estimated at 10,590 (ACS, 2017a). A majority (up to 82%) of those with CLL live 5 to 10 years; however, the presence of complications may shorten survival to 2 to 3 years. The 5-year survival rate for CML increased from 31% in 1992 to 56% for those diagnosed during 2002 to 2008 (National Cancer Institute, SEER, 2017a).
- c. Cost: Estimated national expenditures for care were \$6.3 billion in 2016 (NCI, 2017b).

### G L O S S A R Y

**Anemia:** A low red blood cell (RBC) count. Red blood cells carry oxygen around the body. This condition may contribute to weakness, fatigue, or shortness of breath.

**Blast cell:** Blood cell that is not fully developed and is still immature.

**Leukopenia:** A low white blood cell (WBC) count. A decrease in the production of functional WBCs (leukocytes) weakens the body's immune defense, which can make one more prone to infections.

**Lymphocytic or lymphoblastic:** A cancerous change takes place in a type of marrow cell that forms lymphocytes.

**Lymphopenia:** Low number of lymphocytes in the blood.

**Myelogenous or myeloid:** Cancerous change takes place in a type of marrow cell that normally goes on to form red cells, some types of white cells, and platelets.

**Neutropenia:** Abnormal decrease in the number of neutrophils (type of white blood cell [WBC] that fights infection) in the blood.

**Normocytic, normochromic anemia:** Anemia associated with disturbances of red cell formation and related to endocrine deficiencies, chronic inflammation, and condition in which cancer is spread widely throughout the body or, in some cases, to a relatively large region of the body.

**Progenitor stem cell transplant:** Reestablishment of normal bone marrow function through the infusion of cells committed to forming a specific type of blood cell line—red blood cells (RBCs), WBCs, or platelets. The source of the cells may be from the peripheral blood, bone marrow, or umbilical cord and placenta. The donor may be the client himself or herself (autologous transplant), a genetically compatible relative or individual (allogeneic transplant), or donated cord blood. Syngeneic transplant describes the use of an identical twin as donor.

**Thrombocytopenia:** Disorder in which there are not enough platelets to perform normal clotting functions. This condition is sometimes associated with abnormal bleeding.

**Tumor lysis syndrome (TLS):** Metabolic derangement produced by rapid tumor breakdown as a consequence of therapy. TLS is most likely to occur in clients who have hematologic malignancies (Kaplow & Iyere, 2016). It is characterized by hyperuricemia due to DNA breakdown, hyperkalemia because of cytosol breakdown, hyperphosphatemia because of protein breakdown, and hypocalcemia secondary to hyperphosphatemia. As phosphate level increases, serum calcium decreases. These derangements can result in acute renal failure, cardiac dysrhythmias, and sudden death from hyperkalemia or hypocalcemia.

**CARE SETTING**

Client receives acute inpatient care on medical or oncology unit for initial evaluation and intermittently for treatment, and then care is provided at the community level.

**RELATED CONCERNS**

Cancer, general considerations, page 945

Psychosocial aspects of care, page 835

**CLIENT ASSESSMENT DATABASE**

Data depend on degree and duration of the disease and other organ involvement.

**DIAGNOSTIC DIVISION  
MAY REPORT****MAY EXHIBIT****ACTIVITY/REST**

- Fatigue, increased need for sleep; malaise
- Weakness, inability to engage in usual activities

- Muscle wasting
- Somnolence, lethargy

**CIRCULATION**

- Palpitations

- Tachycardia, heart murmurs
- Pallor of skin, mucous membranes
- Cranial nerve deficits and signs of cerebral hemorrhage

**EGO INTEGRITY**

- Feelings of helplessness, hopelessness

- Mood changes, confusion
- Depression, withdrawal, anxiety, fear, anger, irritability

**ELIMINATION**

- Diarrhea
- Bright red blood or tarry stools
- Perianal tenderness, pain
- Blood in urine, decreased urine output

- Diarrhea
- Bright red blood or tarry stools
- Perianal abscess
- Hematuria

**FOOD/FLUID**

- Loss of appetite, change in taste
- Nausea; vomiting
- Weight loss

- Anorexia; vomiting
- Abdominal distention, enlarged liver or spleen, decreased bowel sounds

**NEUROSENSORY**

- Lack of or decreased coordination
- Muscle cramping
- Dizziness; numbness, tingling, paresthesias
- Mood changes, confusion, disorientation, lack of concentration

- Muscle irritability
- Uncoordinated movements
- Seizure activity
- Mood changes, confusion, disorientation, lack of concentration

**PAIN/DISCOMFORT**

- Abdominal pain
- Bone, joint pain—knees, hips, shoulders, long bones sternum
- Headaches

- Guarding or distraction behaviors, restlessness
- Self-focus

**RESPIRATION**

- Shortness of breath with minimal exertion

- Dyspnea, tachypnea
- Cough
- Decreased breath sounds
- Crackles, rhonchi

**SAFETY**

- History of recent or recurrent infections
- Falls
- Visual disturbances or impairment

- Fever, infections
- Papilledema and exophthalmos; retinal hemorrhages

(continues on page 572)

## CLIENT ASSESSMENT DATABASE (contd.)

### MAY REPORT (continued)

- Nosebleeds or other hemorrhages, spontaneous uncontrollable bleeding with minimal trauma
- Skin and tissue changes
- History of exposure to chemicals—benzene (commercially used toxic liquid that is also present in lead-free gasoline), or excessive levels of ionizing radiation
- Exposure to virus—human T-cell leukemia or lymphoma virus 1 (HTLV-1)

### SEXUALITY

- Changes in libido
- Changes in menstrual flow, menorrhagia
- Testicular pain; impotence

### TEACHING/LEARNING

- Previous treatment with chemotherapy—especially alkalinizing agents
- Chromosomal disorder—Down's syndrome or Fanconi's aplastic anemia

### DISCHARGE PLAN CONSIDERATIONS

- May need assistance with therapy and treatment needs and supplies, shopping, food preparation, self-care activities, homemaker and maintenance tasks, transportation

► Refer to section at end of plan for postdischarge considerations.

### MAY EXHIBIT (continued)

- Bleeding from orifices or tissues
- Gum hypertrophy (may be indicative of AML)
- Petechiae; bruises, purpura
- Leukemic infiltrates (flesh-colored to violet-colored papules, plaques, or nodules in the dermis)
- Jaundice
- Swollen lymph nodes in neck, armpit, or groin

## DIAGNOSTIC STUDIES

### TEST

### WHY IT IS DONE

### WHAT IT TELLS ME

### BLOOD TESTS

- **Complete blood count (CBC):** The most common screening and diagnostic test to demonstrate leukemia. Typically includes hemoglobin (Hgb), hematocrit (Hct), RBC count and morphology and distribution width index, platelet count and size, and WBC count and differential.
- **White blood cell (WBC) count and differential:** Evaluates numbers and characteristics of each of the five types of WBCs: neutrophils, lymphocytes (B cells and T cells), monocytes, eosinophils, and basophils within the bloodstream.
- **Platelet count:** Platelets have essential function in coagulation.

*Note:* Once a diagnosis of leukemia is obtained, additional tests may be performed. These tests may include (and are not limited to) immunophenotyping, fluorescence in situ hybridization (FISH), and IgVH gene mutation test. These more sophisticated tests are not included in this text.

RBC and platelet production is decreased by the leukemic cells and suppression of normal bone marrow activity. WBCs are usually elevated, and in acute leukemia, blasts cells (typically found in bone marrow) may be present in circulating blood.

*Note:* Normally, blasts constitute 5% or less of healthy bone marrow, but in acute, newly diagnosed, or recurrent leukemia, the blasts remain immature and multiply continuously, eventually constituting between 30% and 100% of the bone marrow (Pui et al, 2008).

Persons with ALL or AML often have too many leukocytes—count may be more than 50,000/cm—with increased numbers of immature WBCs (“shift to left”). Leukemic blast cells may be present.

May vary from normal to very low (<50,000/mm). *Note:* Significant bleeding typically does not occur until platelet level drops below 20,000/mm.

WHY IT IS DONE (continued)	WHAT IT TELLS ME (continued)
<ul style="list-style-type: none"> <li><b>Prothrombin time (PT)/activated partial thromboplastin time (aPTT):</b> Determines bleeding and clotting time.</li> <li><b>Blood chemistries:</b> Measures the type and amount of enzymes, minerals, and other substances within the blood.</li> <li><b>Alkaline phosphatase (ALP):</b> Aids in differential diagnosis.</li> <li><b>Lactic dehydrogenase (LDH):</b> Substance released by tumors and found in blood.</li> <li><b>Serum vitamin B<sub>12</sub>:</b> May aid in differential diagnosis of type of leukemia and other myeloproliferative conditions.</li> <li><b>Uric acid:</b> Waste product resulting from the breakdown of nitrogen-containing compounds (purines).</li> </ul>	<p>May be prolonged. Disseminated intravascular coagulation (DIC) may occur with AML, but it is especially common in acute promyelocytic leukemia.</p> <p>Identifies kidney or liver damage that may be caused by leukemic cell breakdown or by drugs used for chemotherapy.</p> <p>Elevated with CML.</p> <p>It is considered an accurate marker for the severity of the disease and used to establish a baseline to monitor for response to treatment.</p> <p>Can be increased with CML and some forms of acute leukemia; normal in CLL and undifferentiated stem cell leukemia.</p> <p>Commonly elevated in client with chemotherapy induction. However, if uric acid is significantly elevated, it is indicative of kidney problems, often associated with tumor lysis syndrome (TLS) (see Glossary).</p>
<ul style="list-style-type: none"> <li><b>X-rays:</b> Determine areas of involvement.</li> </ul>	<p>CT scans are not usually used in client with leukemia unless metastasis is suspected. In such cases, CT scan may detect changes in the lymph nodes around the heart, trachea, or abdomen. Lymph node enlargement is more common in patients with ALL or CLL with potential for compression of organs or internal structures, such as airway obstruction or obstructive uropathy. Scans of liver and spleen may reveal splenomegaly.</p> <p>May reveal enlarged lymph nodes in the chest, a localized mass in the lungs, or evidence that leukemia has spread to bones or joints.</p>
<ul style="list-style-type: none"> <li><b>Bone marrow aspiration and biopsy:</b> May be done by needle aspirate or biopsy for microscopic examination of fluid and tissues within the marrow to determine the number, size, and shape of the various cell types as well as the proportion of mature to immature cells.</li> </ul>	<p>Although signs of leukemia are evident in CBC results and platelet counts, a bone marrow biopsy may be necessary for a definitive diagnosis. The bone marrow examination determines the cell type, the type of erythropoiesis, and the maturity of the leukopoietic and erythropoietic cells.</p>
<h3>DEFINITIVE DIAGNOSTIC STUDIES</h3> <ul style="list-style-type: none"> <li><b>Cytogenetic analysis:</b> Cells are studied to see if chromosomal abnormalities are present.</li> <li><b>Flow cytometry (also called immunophenotyping):</b> Uses antibodies to treat the bone marrow or biopsy samples; specific cells undergo a color change that can be identified under microscope.</li> <li><b>Lumbar puncture:</b> Determines if cancer has spread to spinal column or brain.</li> </ul>	<p>Examination of chromosome abnormalities from samples of peripheral blood, bone marrow, or lymph nodes can indicate prognostic features and direct treatment options.</p> <p>Allows for identification of cells and differentiating characteristics of specific types of leukemia.</p> <p>May reveal leukemic cells in cerebrospinal fluid (CSF).</p>

### NURSING PRIORITIES

1. Prevent infection during acute phases of disease and treatment.
2. Maintain circulating blood volume.
3. Alleviate pain.
4. Promote optimal physical functioning.
5. Provide psychological support.
6. Provide information about disease process, prognosis, and treatment needs.

### DISCHARGE GOALS

1. Complications prevented or minimized.
2. Pain relieved or controlled.
3. Activities of daily living (ADLs) met by self or with assistance.
4. Dealing with disease realistically.
5. Disease process, prognosis, and therapeutic regimen understood.
6. Plan in place to meet needs after discharge.

\*\*\*Refer to CP: Cancer for further discussion and expansion of interventions related to cancer care and for client teaching.

## NURSING DIAGNOSIS: risk for Infection

### Possibly Evidenced By

Stasis of body fluids, traumatized tissue, invasive procedures  
Immature WBCs with low granulocyte and abnormal/immature lymphocyte count; immunosuppression, bone marrow suppression; pharmaceutical agents  
Malnutrition; chronic disease

### Desired Outcomes/Evaluation Criteria—Client Will

#### Risk Control: Infectious Process NOC

Identify actions to prevent or reduce risk of infection.

Demonstrate techniques or lifestyle changes to promote safe environment and achieve timely healing.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Infection Protection NIC</b> <i>Independent</i> Place in private room. Screen and limit visitors, as indicated. Prohibit use of live plants or cut flowers. Restrict fresh fruits and vegetables or make sure they are washed or peeled.	Protect client from potential sources of pathogens and infection. Note: Profound bone marrow suppression, neutropenia, and chemotherapy place client at great risk for infection.
Model and require good handwashing protocol for all personnel and visitors.	Prevents cross-contamination and reduces risk of infection.
Monitor temperature. Note correlation between temperature elevations and chemotherapy treatments. Observe for fever associated with tachycardia, hypotension, and subtle mental changes.	Although fever may accompany some forms of chemotherapy, progressive hyperthermia occurs in some types of infections, and fever unrelated to drugs or blood products occurs in most leukemia clients. Note: Septicemia may occur without fever.
Prevent chilling. Force fluids and administer tepid sponge bath.	Helps reduce fever, which contributes to fluid imbalance, discomfort, and central nervous system (CNS) complications.
Encourage frequent turning and deep breathing.	Prevents stasis of respiratory secretions, reducing risk of atelectasis and pneumonia.
Auscultate breath sounds, noting crackles and rhonchi; inspect secretions for changes in characteristics, such as increased sputum production or change in sputum color. Observe urine for signs of infection: cloudy, foul smelling, or presence of urgency or burning with voids.	Early intervention is essential to prevent sepsis or septicemia in immunosuppressed person.
Handle client gently. Keep linens dry and wrinkle-free.	Prevents sheet burns (friction injury) and skin excoriation.
Inspect skin for tender, erythematous areas and open wounds. Cleanse skin with appropriate antibacterial solutions.	May indicate local infection. Note: Open wounds may not produce pus because of insufficient number of granulocytes.
Inspect oral mucous membranes. Provide good oral hygiene. Use a soft toothbrush, sponge, or swabs for frequent mouth care.	The oral cavity is an excellent medium for growth of organisms and is susceptible to ulceration and bleeding.
Promote good perianal hygiene. Examine perianal area at least daily during acute illness. Provide sitz baths, using Betadine or Hibiclens™, if indicated. Avoid rectal temperatures and use of suppositories.	Promotes cleanliness, reducing risk of perianal abscess; enhances circulation and healing. Note: Perianal abscess can contribute to septicemia and death in immunosuppressed clients.
Coordinate procedures and tests to allow for uninterrupted rest periods.	Conserves energy for healing and cellular regeneration.
Encourage increased intake of fluids and foods high in protein with adequate fiber.	Promotes healing and prevents dehydration. Note: Constipation potentiates retention of toxins and risk of rectal irritation and tissue injury.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Prepare for/assist with invasive procedures, such as venipuncture, insertion of semipermanent central lines or ports, maintaining sterile technique for insertions and site care per protocol.	Break in skin could provide an entry for pathogenic and potentially lethal organisms. Use of central venous lines, such as tunneled catheter or implanted port, can effectively reduce need for frequent invasive procedures and risk of infection. Note: Myelosuppression may be cumulative in nature, especially when multiple drug therapy, including steroids, is prescribed.
<b>Collaborative</b>	
Monitor laboratory studies, such as the following:	
CBC, noting whether WBC count falls or sudden changes occur in neutrophils	Decreased numbers of normal or mature WBCs can result from the disease process or chemotherapy, compromising the immune response and increasing risk of infection.
Gram's stain cultures and sensitivity	Verifies presence of infections; identifies specific organisms and appropriate therapy.
Review serial chest x-rays.	Indicator of development or resolution of respiratory complications.
Prepare for and assist with leukemia-specific treatments, such as chemotherapy with neoplastic agents; biological therapy (immune modulators [such as interferons] and gene-directed agents [such as imatinib]); radiation, bone marrow and stem cell transplantation. (Refer to ND: deficient Knowledge at end of this care plan for information regarding leukemia-specific medications and other treatments.)	Leukemia treatment falls into two categories: (1) treatment to fight the cancer and (2) treatment to relieve symptoms of the disease and the side effects of therapy (supportive care). A variety of treatment options are available, depending on the type and phase of the client's disease. The most widely used antileukemic treatment is chemotherapy (of which there are many different drugs), typically given in cycles, sometimes referred to as induction, consolidation, and maintenance (Hu, 2016; Seiter, 2017).
Administer other medications, as indicated, for example:	
Anti-infectives, such as ofloxacin (Ocuflax) and rifampin (Rifadin)	May be given prophylactically or to treat specific infection, especially in febrile client who has prolonged granulocytopenia or too few mature neutrophils (Seiter, 2017).
Colony-stimulating factors (CSFs), such as sargramostim (Leukine), filgrastim (Neupogen), and pegfilgrastim (Neulasta)	Restores WBCs destroyed by chemotherapy and reduces risk of severe infection and death in certain types of leukemia.
Avoid use of aspirin-containing antipyretics.	Aspirin can cause gastric bleeding and further decrease platelet count.
Provide nutritious diet, high in protein and calories, avoiding raw fruits, vegetables, or uncooked meats.	Proper nutrition enhances immune system. Minimizes potential sources of bacterial contamination.

### NURSING DIAGNOSIS: risk for deficient Fluid Volume

#### Possibly Evidenced By

[Hypertonic or hypotonic dehydration associated with chronic illness, malnutrition, inadequate free water, renal insufficiency or failure]; compromised regulatory system  
Active fluid loss—vomiting, hemorrhage, diarrhea  
Insufficient fluid intake—nausea, anorexia  
Factors influencing fluid needs—hypermetabolic state, fever, predisposition for kidney stone formation and tumor lysis syndrome

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Hydration NOC

Demonstrate adequate fluid volume, as evidenced by stable vital signs; palpable pulses; urine output, specific gravity, and pH within normal limits.

##### Risk Control: Dehydration NOC

Identify individual risk factors and appropriate interventions.  
Initiate behaviors or lifestyle changes to prevent development of dehydration.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Fluid Management NIC</b>	
<i>Independent</i>	
Monitor intake and output (I&O). Calculate insensible losses and fluid balance. Note decreased urine output in the presence of adequate hydration.	These symptoms can occur if circulating volume depletion (shock) is present or if complications of chemotherapy are occurring. Note: In the setting of chemotherapy induction, kidney function can be impaired by tumor lysis syndrome (TLS). TLS is the result of cancer cells being destroyed, resulting in toxins (from cell death), and the release of large amounts of potassium, phosphate, and nucleic acids into systemic circulation. This process impairs kidney renal tubular function and filtration (acute kidney injury), potentially leading to renal failure. TLS is an oncologic emergency (Larson & Pui, 2017).
Weigh daily.	Measure of adequacy of fluid replacement and kidney function. Continued intake greater than output may indicate renal insult or obstruction.
Monitor blood pressure (BP) and heart rate.	Changes may reflect effects of hypovolemia associated with bleeding or dehydration.
Evaluate skin turgor, capillary refill, and general condition of mucous membranes.	Indirect indicators of fluid status.
Note presence of nausea or fever.	Affects intake, fluid needs, and route of replacement.
Encourage liberal fluids when oral intake is resumed.	Promotes urine flow, prevents uric acid precipitation, and enhances clearance of antineoplastic drugs.
<b>Bleeding Precautions NIC</b>	
Inspect skin and mucous membranes for petechiae and ecchymotic areas; note bleeding gums, frank or occult blood in stools and urine, and oozing from invasive line sites.	Suppression of bone marrow and platelet production places client at risk for spontaneous or uncontrolled bleeding.
Implement measures to prevent tissue injury and bleeding: gentle brushing of teeth or gums with soft toothbrush, cotton swab, or sponge-tipped applicator; using electric razor instead of sharp razors when shaving; avoiding forceful nose blowing and needlesticks when possible; and using sustained pressure such as sandbags or pressure dressings on oozing puncture or intravenous (IV) sites.	Fragile tissues and altered clotting mechanisms increase the risk of hemorrhage following even minor trauma.
Limit oral care to mouth rinse, if indicated, such as a mixture of 1/4 tsp baking soda and 1/8 tsp salt in 8 oz water, or may use hydrogen peroxide in water or saline for bleeding or infected oral tissue. Avoid mouthwashes with alcohol.	When bleeding is present, even gentle brushing may cause more tissue damage. Alcohol has a drying effect and may be painful to irritated tissues.
Provide soft foods.	May help reduce risk of gum bleeding.
<b>Fluid Management NIC</b>	
<i>Collaborative</i>	
Administer IV and electrolyte solutions, as indicated.	Maintains fluid and electrolyte balance in the absence of oral intake. Hydration prevents or minimizes tumor lysis syndrome and reduces risk of renal complications. The goal of IV hydration is to improve renal perfusion and glomerular filtration, and induce a high urine output to minimize the likelihood of uric acid or calcium phosphate precipitation in the tubules. Note: IV hydration can lead to potentially dangerous fluid overload in patients with underlying acute kidney injury or cardiac dysfunction (particularly if the patient is in an edematous state). In this setting, close monitoring of vital signs and urine output is mandatory, transfusion (if needed) should be given slowly and in low volume, and diuretics can be given to maintain urine output.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Administer medications, as indicated, for example: Antiemetics: such as ondansetron (Zofran), inapsine (Droperidol), aprepitant (Emend), and dronabinol (Marinol)	Chemotherapy-induced nausea and vomiting (CINV) is one of the most feared side effects of chemotherapy. With the correct use of antiemetics, CINV can be prevented in 70% to 80% of patients (NCI, 2017d; Jordan et al, 2014). Relieving nausea and vomiting can reduce fluid deficits and enhance oral intake.
Allopurinol (Zyloprim), rasburicase (Elitek)	Drugs such as these may be given prophylactically to prevent TLS at chemotherapy induction and duration of treatment or to improve renal excretion of toxic by-products from tumor lysis. Reduces the chances of nephropathy as a result of uric acid production.
<b>Bleeding Precautions NIC</b> Monitor laboratory studies, including red blood cells, platelets, and Hgb/Hct.	Low red blood cell counts can be associated with the leukemia (anemia because of reduction/in/destruction of bone marrow cells). If Hgb and Hct are both decreased, bleeding may be occurring. Platelets are the blood cells responsible for blood clotting. When the platelet count is less than 20,000/mm <sup>3</sup> because of proliferation of WBCs or bone marrow suppression, client is prone to spontaneous bleeding.
Assist with insertion/maintain central vascular access device, such as subclavian or tunneled catheter or implanted port, as indicated.	Client with leukemia may require central vascular access to ensure delivery of intravenous therapy and to eliminate peripheral venipuncture as source of bleeding.
Administer packed RBCs, platelets, and clotting factors.	Transfusions may be required from time to time to correct anemia and support clotting. Platelets or fresh-frozen plasma (FFP) may be used to prevent or treat hemorrhage (Seiter, 2017).

**NURSING DIAGNOSIS:** acute Pain**May Be Related To**

Physical agents—enlarged organs and lymph nodes, bone marrow packed with leukemic cells

Chemical agents—antileukemic treatments

Psychological—anxiety, fear

**Possibly Evidenced By**

Verbalized/coded reports of pain

Guarding behaviors

Expressive behaviors—facial grimacing, restlessness

Changes in vital signs

**Desired Outcomes/Evaluation Criteria—Client Will****Pain Level NOC**

Report pain is relieved or controlled.

Appear relaxed and able to sleep and rest appropriately.

**Pain Control NOC**

Demonstrate behaviors to manage pain.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Pain Management: Acute NIC</b> <i>Independent</i> Investigate reports of pain. Note changes in intensity (using 0 to 10 [or similar] scale) and location of pain.	Helpful in understanding client's situation and intervention needs and monitoring potential of developing complications.

(continues on page 578)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Monitor vital signs, noting changes in blood pressure, heart rate, and breathing pattern. Note nonverbal cues, such as facial mask of pain, grimacing, crying, withdrawal, muscle tension, and restlessness.	Indicators of acute pain that can corroborate verbal reports or may be only indicators in client unable or unwilling to verbalize pain. Client with long-term condition may have acute pain superimposed on chronic pain issues and be reluctant to report new symptoms. Older client may or may not report pain but may have more pain behaviors.
Determine client's acceptable level of pain and help client achieve pain control.	Pain is a subjective experience and needs to be fully addressed by care providers to promote the best possible quality of life. Client may report having a level of discomfort that is manageable (e.g., can do desired activities when pain is reduced from a 10 to a 3). Another client may need to be pain-free in order to function.
Provide quiet environment and reduce stressful stimuli: noise, lighting, and constant interruptions.	Promotes rest and enhances coping abilities.
Place in position of comfort, and support joints and extremities with pillows and other padding.	May decrease associated bone and joint discomfort.
Reposition periodically and provide or assist with gentle range-of-motion (ROM) exercises.	Improves tissue circulation and joint mobility.
Provide comfort measures, such as massage, cool packs, and psychological support, including encouragement and presence, as appropriate.	Nonpharmacologic measures can enhance effects of medication.
Review and promote client's own comfort interventions—position and physical activity or nonactivity.	Successful management of pain requires client involvement. Use of effective techniques provides positive reinforcement, promotes sense of control, and prepares client for interventions to be used after discharge.
Evaluate and support client's coping mechanisms.	Using own learned perceptions and behaviors to manage pain can help client cope more effectively.
Encourage use of stress management techniques, such as deep-breathing exercises, guided imagery, visualization, and Therapeutic Touch.	Facilitates relaxation, augments pharmacological therapy, and enhances coping abilities.
Assist with or provide diversional activities and relaxation techniques.	Helps with pain management by redirecting attention.
<b>Collaborative</b>	
Monitor uric acid level as appropriate.	Rapid turnover and destruction of leukemic cells during chemotherapy can elevate uric acid, causing swollen painful joints in some clients. Note: Massive infiltration of WBCs into joints can also result in intense pain.
Administer medications, as indicated, for example:	
Analgesics, such as acetaminophen (Tylenol)	Given for mild pain not relieved by comfort measures. Note: Avoid aspirin-containing products because they may potentiate hemorrhage.
Opioids, such as codeine, morphine, and hydromorphone (Dilaudid)	Routinely scheduled medication administration or patient-controlled analgesia (PCA) is beneficial in preventing peaks and valleys associated with intermittent drug administration and increases client's sense of control.
Antianxiety agents, such as diazepam (Valium) and lorazepam (Ativan)	May be given to enhance the action of analgesics and opioids.

## NURSING DIAGNOSIS: Fatigue

### May Be Related To

Physiological condition (e.g., disease state; malnutrition; anemia)  
 Stressors; anxiety; negative life events; sleep deprivation  
 Altered body chemistry (e.g., medications, chemotherapy)

**NURSING DIAGNOSIS:** **Fatigue** (continued)**Possibly Evidenced By**

Insufficient energy; impaired ability to maintain usual routines or physical activity  
Tiredness, nonrestorative sleep pattern; increase in physical symptoms  
Lethargy; apathy; drowsiness; alteration in concentration  
Disinterest in surroundings; ineffective role performance

**Desired Outcomes/Evaluation Criteria—Client Will****Fatigue Level NOC**

Report improved sense of energy; measurable increase in activity tolerance.  
Participate in ADLs to level of ability.  
Demonstrate a decrease in physiological signs of intolerance—pulse, respiration, and BP remain within client's normal range.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Energy Management NIC</b> <i>Independent</i> Be aware of client's particular type and severity of leukemia, as well as typical treatment-related symptoms and/or side effects.	Cancer-related fatigue (CRF) is one of the most common side effects of cancer and its treatments and can affect client in varying degrees of magnitude and at different times.
Evaluate and document client's reports of fatigue, using fatigue inventory or numeric (or similar scale), noting client's account of inability to participate in desired activities. Determine alleviating and exacerbating factors.	Evaluation and documentation of subjective reports and objective signs of fatigue are useful for the client and necessary for healthcare provider to establish baseline and effects of interventions. Effects of the disease process, anemia, tumor-induced toxins, pain, depression, and malnutrition associated with chemotherapy can be cumulative, especially during acute and active treatment phase (NCI, 2017d). Note: CRF often comes on suddenly, does not result from activity or exertion, and is not relieved by rest or sleep.
Note client's nutritional status, including appetite, ability and desire to eat, current weight, presence of generalized and muscle weakness.	Factors interfering with intake of needed nutrients can exacerbate fatigue.
Assess for pain and effectiveness of pain management interventions. Note side effects of prescribed analgesics.	Unrelieved pain often increases fatigue. And while pharmacologic pain management can improve client's sense of energy, the medications themselves can exacerbate fatigue.
Determine presence of/client's level of emotional distress (e.g., frustration, fear, anxiety, depression).	Many stressors are associated with the disease process, treatments and treatment-related symptoms, and lifestyle impact. Interventions are needed ongoing (both within and without medications) to promote client's emotional comfort and reduce associated fatigue.
Active-listen to client/SO concerns and coping. Provide information about disease process and desired treatment responses. Provide supportive presence and interventions.	Client may or may not have information about disease process or expectations for treatment. Information (e.g., that sometimes treating the anemia can reduce the fatigue) can improve client/SO's coping abilities. Additional supportive interventions may be needed when client is severely ill or fatigue is chronic.
Encourage client at home to keep a diary of daily routines and energy levels for 1 week, noting activities that increase fatigue.	Helps client prioritize activities and arrange them around fatigue pattern.
Provide quiet environment for sleep and uninterrupted rest periods. Encourage rest periods before activities known to increase fatigue.	Restores energy needed for activity and cellular regeneration and tissue healing.

(continues on page 580)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Implement (and teach) energy-saving techniques, such as sitting rather than standing, or alternate; use shower chair and furniture with good support; combine activities, reducing number of individual actions, reduce sudden or prolonged strains, and so on. Assist with ambulation or other activities, as indicated.	Maximizes available energy for self-care tasks.
Recommend frequent small, nutritious, high-protein meals and snacks throughout the day if client is able to eat.	Smaller meals require less energy for ingestion and digestion than larger meals. Increased intake provides fuel for energy. (Refer to CP: Cancer, general considerations: ND: imbalanced Nutrition: less than body requirements.)
Determine presence and level of attentional fatigue. Provide and encourage use of diversional activities, as tolerated and desired.	The planned use of attention-restoring activities (e.g., watching grandchildren play, following a simple recipe, attending a movie, window gardening) can improve mood and fatigue associated with inactivity and depression.
<b>Collaborative</b> Review laboratory studies (initial and ongoing) such as CBC and red blood cell indices, nutrition state indicators, and vitamin levels.	These lab values (among others) can help identify presence/degree of anemia and other disease- or treatment-related factors associated with fatigue.
Refer to appropriate medical providers, and assist in management of underlying condition, as indicated.	Sometimes treating the disease symptoms (e.g., anemia) will relieve the fatigue. But other interventions may be needed over time, such as discontinuation of certain anticancer drugs, implementation of dietary changes, and titration of pain medications, initiation of physical activity (e.g., graded walking program) to manage fatigue and its effect on client's quality of life.
Administer medications (e.g., nutrient components and vitamin supplements; psychostimulants and antidepressants), as indicated.	Enteral/parenteral feedings, supplemental protein, calories, or vitamins can improve energy, and medications to manage emotional issues/depression can improve mood and reduce fatigue (NCI, 2017a).
Provide supplemental oxygen, as indicated.	Maximizes oxygen available for cellular uptake, improving tolerance of activity, especially in the setting of severe anemia, cardiopulmonary or renal complications.
Administer blood and blood components, as indicated.	Correcting anemia can improve client's stamina and tolerance for activity.

### NURSING DIAGNOSIS: **deficient Knowledge regarding disease, prognosis, treatment, self-care, and discharge needs**

#### May Be Related To

Insufficient information/knowledge of resources  
Information misinterpretation

#### Possibly Evidenced By

Insufficient knowledge  
Inaccurate follow-through of instructions

#### Desired Outcomes/Evaluation Criteria—Client Will

##### **Knowledge: Acute Illness Care/Knowledge: Chronic Disease Management NOC**

Verbalize understanding of condition, disease process, and potential complications.  
Verbalize understanding of therapeutic needs.  
Initiate necessary lifestyle changes.  
Participate in treatment regimen.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Teaching: Disease Process NIC</b> <i>Independent</i> Review client's specific form of leukemia and treatment plan, including:  Medications, using newer classes of drugs such as <b>Bcr-Abl tyrosine kinase inhibitors</b> (e.g., imatinib mesylate [Gleevec], dasatinib [Sprycel]); <b>histone deacetylase inhibitors (HDACs)</b> (e.g., vorinostat [Zolinza]); <b>hypomethylating or demethylating agents</b> (e.g., azacitidine [Vidaza] and decitabine [Dacogen]); <b>immunomodulators</b> (e.g., lenalidomide [Revlimid], thalidomide [Thalomid]); <b>monoclonal antibodies</b> (e.g., rituximab [Rituxan]); <b>antibody-drug conjugates</b> (e.g., brentuximab vedotin [Adcetris]); <b>proteasome inhibitors</b> (e.g., bortezomib [Velcade] and carfilzomib [Kyprolis]); <b>chemotherapy agents</b> (e.g., daunorubicin [Cerubidine], mitoxantrone cytarabine [Novantone], idarubicin [Idamycin])	Treatments can include various individual and combinations of therapies.  In the past 10 years, several new drugs (and new uses for established drugs) have greatly improved rates of blood cancer cure and remission (LLS, 2014–2015). Many treatments are targeted to the specific cancer, and combining treating agents is common (Hu, 2016; LLS, 2014–2015; Seiter, 2017).
Radiation therapy	Kills cancer cells by exposure to high-energy radiation. Radiation therapy is typically part of a treatment program including drugs.
Gene therapy	Gene therapy alters a gene's DNA or RNA expression to disable oncogenes (see Glossary) and prevents the formation of corresponding oncoproteins. Gene therapy is considered "personalized medicine" that can be applied if there is enough information about the individual and/or the specific disease to tailor the treatment (LLS, 2014–2015).
Stem cell transplantation (SCT), including peripheral stem cell transplant or umbilical cord blood transplant	After chemotherapy and/or radiation, the injured bone marrow is replenished by a transplant of stem cells, which can manufacture the necessary new blood cells. Stem cell transplantation may be autologous (uses client's own stem cells) or allogenic (donor cells).
Surgery	While rare, surgery may be performed to remove an enlarged spleen or to install a venous access device to give medications and withdraw blood samples (Swierzewski, 2015).
Discuss side effects of treatment, as indicated, and possible solutions.	Client may want opportunity to prepare for certain side effects, such as temporary hair loss. Client and significant other (SO) may benefit from knowledge that certain discomforts, such as nausea, vomiting, weakness, mouth sores, bruising, and anorexia, are treatment related, not indications of escalating disease, and will subside.
Inform client and SO of potential sexual side effects of treatment and provide opportunity to consider options. Discuss sperm banking and pregnancy issues, when appropriate, before beginning treatment.	In males, permanent sterility can occur as a result of radiation when combined with certain chemotherapeutic agents. In females, menstruation may cease during the active phase of treatment, with older women subsequently experiencing menopause. Pregnancy should be avoided during treatment and for 2 to 3 years after treatment as that is when recurrence is most common. Vaginal dryness can be a distressing side effect as well.

For additional interventions, refer to CP: Cancer: General Considerations; ND: deficient Knowledge.

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

- **risk for Infection**—alterations in mature WBCs (low granulocyte and abnormal lymphocyte count), increased number of immature lymphocytes, immunosuppression, bone marrow suppression (effects of therapy/transplant)
- **ineffective Role Performance**—situational crisis, physical illness, fatigue, stressors
- **ineffective Health Management**—difficulty managing complex treatment regimen, decisional conflicts, excessive demands, perceived benefit, powerlessness economically disadvantaged
- **interrupted Family Processes**—situational crisis (illness, disabling and expensive treatments); shift in health status of a family member, shift in family roles

## ADULT LYMPHOMAS

### I. Pathophysiology

- a. **Lymphoma** is a general term for many blood cancers that originate in the lymphatic system.
- b. Malignant growth involving reticuloendothelial and lymphoid system, resulting in accumulation of abnormal lymphocytes in lymph tissue forming masses; may travel to distant sites, including the lungs, liver, gastrointestinal (GI) tract, meninges, skin, and bones (NCI, 2017c).
- c. Major sites of lymphoid tissue are lymph nodes, spleen, thymus gland, adenoids and tonsils, and digestive tract. Lymphoma is the second most common primary malignancy occurring in the head and neck (Dunleavy, Kass, & Wilson, 2017).

### II. Classifications and treatments (Dunleavy et al, 2017; LSS, 2014–2015)

- a. Lymphomas are divided into two major categories: Hodgkin's lymphoma (HL), formerly called Hodgkin's disease, and non-Hodgkin's lymphoma (NHL).
- b. Staging (typically using the Ann Arbor Staging system I–IV) provides a general idea of how far the disease has spread and how it should be treated. This is done after testing determines which parts of the body are affected.
- c. Letters of the alphabet are also used in conjunction with the stage to further describe the lymphoma. The most important ones are A and B. For example, if the client complains of fever, weight loss, or excessive night sweats (called "B" symptoms), a "B" is added to the stage description. If none of these symptoms exist, an "A" is added. If any organ that does not belong to the lymph system is involved, it is denoted with an "E" for extranodal (organ involvement) after the stage. If the spleen is involved, the corresponding letter is "S." An "X" designation is used for bulky lymphadenopathy (a cancer with considerable tumor masses that may be felt or seen) (Dunleavy et al, 2017).
- i. Hodgkin's lymphoma (HL) is divided into two main classifications: (1) classical HL (CHL), which accounts for most cases of HL, and (2) nodular lymphocyte-predominant HL.
  1. A characteristic that distinguishes CHL is the presence of a large malignant cell called the Reed-Sternberg (R-S) cell. This characteristic does not appear in nodular lymphocyte-predominant HL.
  2. HL status is grouped for treatment (after staging) as early favorable, early unfavorable, and advanced.
  3. HL is now considered to be one of the most curable forms of cancer.

4. **HL treatments** for early stage (I and II) HL include some form of chemotherapy (usually combinations of drugs), plus limited radiation (external or internal involved field or site) therapy, and sometimes bone marrow transplantation (BMT) and peripheral blood stem cell transplantation (PBSCT). Treatment for advanced stage HL is typically combination chemotherapy (Canellos, 2016; LymphomaInfo.net, 2016; PDQ™ Adult Treatment Editorial Board, 2017).

- ii. Non-Hodgkin's lymphoma (NHL) (LSS, 2014–2015; PDQ™ Adult Editorial Board, 2017)
  1. Most common cancer of the lymphatic system
  2. Incidence is consistently higher than HL, with NHL the sixth most common cancer in the United States (LSS, 2014–2015).
  3. Divided into two broad categories: B-cell or T-cell lymphomas. B-cell lymphomas develop from abnormal B cells and account for 85% of all NHLs. T-cell lymphomas develop from abnormal T cells and account for the remaining 15% of all NHLs.
  4. B-cell lymphomas are designated as indolent (slow-growing) or (fast-growing).
    - a. **Indolent B-cell lymphomas:** These lymphomas are characterized by a slow progression because the client can remain well for several years without therapy. These lymphomas include multiple subtypes (e.g., cutaneous T cell, follicular, and small lymphocytic [SLL]). Indolent lymphomas are, however, usually not considered curable because the cancer grows too slowly to be targeted accurately by most conventional therapies (Cyberfamily Staff, 2017).
    - b. **Aggressive B-cell lymphomas:** These include diffuse large B-cell lymphoma (DLBC), and Burkitt's, mantle-cell, and lymphoblastic lymphomas. DLBC is the most common type of NHL, making up about 30% of all lymphomas (Freedman & Friedberg, 2017). The standard treatment of advanced DLBCL is combination chemotherapy plus immunotherapy.
  5. **NHL treatments** differ from person to person, depending on the type and stage and whether the disease is indolent or aggressive. In general, treatments include chemotherapy, radiation (whole body or specific zone), newer versions of

established agents, immunotherapy (such as monoclonal antibody therapy [Mab]), radioimmunotherapy (which combines radiotherapy with monoclonal antibody therapy), and stem cell bone marrow transplantation. Surgery may be performed to remove the lymphoma in certain circumstances (e.g., gastrointestinal lymphoma with perforation, or splenectomy) (Duleavy et al, 2017; LymphomaInfo.net, 2016; PDQ™ Adult Editorial Board, 2017).

### III. Etiology

- Exact causes are unknown.
- Several factors have been linked to an increased risk (Iarocci, 2017; Mayo Clinic Staff, 2017).
  - Age:** Risk of NHL generally increases with advancing age. It is most common in people 60 or older and is greatly increased in people between the ages of 80 and 84 (LLS, 2014–2015).
  - Infections:** Bacteria, viruses, and parasites have all been implicated in the development of various lymphomas, including HL and NHL. For example, human T-lymphocytic virus type 1 (HTLV-1) has been linked to adult T-cell leukemia-lymphoma (ATL); Epstein-Barr virus (EBV) has been linked to Burkitt's lymphoma; *Helicobacter pylori* (*H. pylori*) has been linked to

gastric lymphoma of mucosa-associated lymphoid tissue (MALT), a rare type of NHL.

- Medical conditions that suppress the immune system, such as HIV, rheumatoid arthritis; conditions requiring immunosuppressive therapy, such as organ transplantation
- Exposure to toxic chemicals: occupational exposure to pesticides, herbicides, or benzene and other solvents; woodworking

### IV. Statistics

- Morbidity:** In 2017, there were an estimated 630,037 people living with non-Hodgkin's lymphoma in the United States and 186,607 people living with Hodgkin's lymphoma (LLS, 2016–2017). The National Cancer Institute SEER report estimated 72,240 new cases of NH for 2017. Cancer.net estimated that 8260 people would be diagnosed with HL in 2017. The 5-year survival rate, according to Cancer.net, is 85% to 87% for HL and, according to SEER, is 71% for NHL.
- Mortality:** In 2017, according to SEER and Cancer.net, there were an estimated 21,200 deaths (1060 from HL and 20,140 from NHL).
- Cost:** In 2016, the national direct costs for care were an estimated \$14 billion (NCI, 2017b).

## GLOSSARY

**Bone marrow transplant (BMT):** Bone marrow is taken from a compatible donor or the client's own body, prior to high-dose chemotherapy and/or radiation treatment. After treatment, the marrow, which may or may not have been treated with chemotherapy, is reinfused into the patient to restore the immune system.

**Erythroderma:** Generalized redness (erythema) of the skin involving more than 90% of the body surface with variable scaliness (lesions). Skin is red and warm to touch. Client appears uncomfortable, with complaints of intense skin itching and pain and of feeling cold. The most common malignant cause is cutaneous T-cell lymphoma (CTCL) (Mistry et al, 2015).

**Hilar lymphadenopathy:** Enlargement of the tracheobronchial and pulmonary lymph nodes.

**Lymphopenia:** Low number of lymphocytes in the blood.

**Neuralgia:** Pain in the distribution of a nerve or nerve pathway.

**Normocytic, normochromic anemia:** Anemia associated with disturbances of red blood cell (RBC) formation, which is related to endocrine deficiencies, chronic inflammation, and condition in which cancer is spread widely throughout the body or, in some cases, to a relatively large region of the body.

**Pel-Ebstein fever:** Fever pattern common in HL, in which temperature varies during each 24-hour period but never reaches normal.

**Peripheral blood cell transplantation:** The most common form of stem cell transplant with the source of stem cells being the circulating blood, rather than the bone marrow. Client with NHL can have either an autologous or an

allogeneic peripheral blood cell transplant, depending on whether or not his or her own stem cells are suitable for use and whether a suitable donor can be found.

**Stem cell transplant:** Reestablishment of normal bone marrow function through the infusion of cells committed to forming a specific type of blood cell line—RBCs, white blood cells (WBCs), or platelets. The source of the cells may be from the peripheral blood, bone marrow, or umbilical cord and placenta. The donor may be the client (autologous transplant), a genetically compatible relative or individual (allogeneic transplant), or donated cord blood. Syngeneic transplant describes the use of an identical twin as donor.

**Superior vena cava syndrome (SVC):** Obstruction of venous drainage from enlarged lymph nodes due to lymphoma disease.

**Tumor lysis syndrome:** Metabolic derangement produced by rapid tumor breakdown as a consequence of therapy for some lymphomas (e.g., Burkitt's lymphoma, lymphoblastic lymphoma, or B-cell acute lymphoblastic leukemia). It is characterized by hyperuricemia because of DNA breakdown, hyperkalemia because of cytosol breakdown, hyperphosphatemia because of protein breakdown, and hypocalcemia secondary to hyperphosphatemia. As phosphate level goes up, serum calcium goes down. These derangements can result in acute renal failure, cardiac dysrhythmias, and sudden death from hyperkalemia or hypocalcemia. *Note:* In studies, laboratory evidence of TLS has been found much more frequently (42%) than the clinical symptoms of TLS (6%) (Ikeda et al, 2017).

## CARE SETTING

The client receives acute inpatient care on a medical unit for initial evaluation and treatment and then at the community level. This plan of care addresses potential complications that may be encountered in acute care or palliative settings.

## RELATED CONCERNS

Adult leukemias, page 569  
Anemias—iron deficiency, anemia of chronic disease, pernicious, aplastic, hemolytic, page 541  
Cancer: general considerations, page 945  
Psychosocial aspects of care, page 835  
Sepsis/septic shock, page 772  
Upper gastrointestinal bleeding, page 340

## CLIENT ASSESSMENT DATABASE

### DIAGNOSTIC DIVISION MAY REPORT

### MAY EXHIBIT

#### ACTIVITY/REST

- Fatigue
- Weakness or general malaise
- Loss of productivity and decreased exercise tolerance

- Diminished strength, slumping of the shoulders, slow walk, and other cues indicative of fatigue

#### CIRCULATION

- Palpitations, chest pain
- Painless swelling of one or more lymph nodes (common early sign in both HL and NHL)

- Tachycardia, dysrhythmias
- Painless swelling of the lymph nodes, beginning in the neck and progressing to axillary, inguinal, mediastinal, and mesenteric regions
- Cyanosis and edema of the face and neck or arms due to superior vena cava syndrome, a rare occurrence, but more common in lymphomas with large mediastinal mass
- Pallor
- Diaphoresis, night sweats

#### EGO INTEGRITY

- Increased stress from school, job, family
- Fear related to diagnosis and possibility of dying
- Concerns about diagnostic testing and treatment modalities—chemotherapy, radiation therapy, surgery
- Financial concerns—hospital costs, treatment expenses, fear of losing job-related benefits because of lost time from work
- Relationship status—fear and anxiety related to being a burden on family and significant other (SO)

- Varied behaviors—angry, withdrawn, passive

#### ELIMINATION

- Changes in characteristics of urine or stool
- History of intestinal obstruction, such as intussusception or malabsorption syndrome (infiltration from retroperitoneal lymph nodes)

- Decreased output, dark and concentrated urine, anuria
- Abdomen: Right upper quadrant (RUQ) tenderness and enlargement on palpation (hepatomegaly); left upper quadrant (LUQ) tenderness and enlargement on palpation (splenomegaly)
- Bowel and bladder dysfunction (spinal cord compression occurs late)

#### FOOD/FLUID

- Anorexia
- Dysphagia (pressure on the esophagus)
- Severe nausea and vomiting, often treatment related
- Recent unexplained weight loss
- Drenching night sweats of whole body (HL)

- Abdominal distention, enlarged spleen (NHL)
- Ascites and edema of the lower extremities (inferior vena cava obstruction from intra-abdominal lymph node enlargement associated with NHL)

**MAY REPORT (continued)****MAY EXHIBIT (continued)****NEUROSENSORY**

- Nerve pain reflecting compression of nerve roots by enlarged lymph nodes in the brachial, lumbar, and sacral plexuses
- Muscle weakness, paresthesia

**PAIN/DISCOMFORT**

- Bone pain (NHL)
- Tenderness or pain over involved lymph nodes—in or around the mediastinum (chest)
- Stiff neck
- Abdominal pain (NHL)

**RESPIRATION**

- Dyspnea on exertion or at rest, chest pain
- Persistent cough with shortness of breath (HL)

**SAFETY**

- History of frequent or recurrent infections (abnormalities in cellular immunity predispose client to systemic herpes virus infections, tuberculosis [TB], toxoplasmosis, or bacterial infections); history of infectious mononucleosis (higher risk of HL in client with high titers of EBV)
- HIV positive: Risk of NHL is higher in these clients compared with the general population. However, antiretroviral therapy (ART) has cut the rate of NHL in HIV-positive people significantly (Blahd, 2016).
- Administration of immunosuppressive drugs after organ transplantation
- History or presence of ulcers, *H. pylori*
- Waxing and waning pattern of lymph node size
- Cyclical pattern of evening temperature elevations lasting a few days to weeks (Pel-Ebstein fever) followed by alternate afebrile periods; drenching night sweats without chills
- Rash, itching
- Whole-body red, itchy skin

**SEXUALITY**

- Concerns about sterility, fertility, and pregnancy
- Decreased libido

**TEACHING/LEARNING**

- Familial risk factors—higher incidence of HL among families than in general population
- Occupational exposure to pesticides and herbicides or other chemicals—benzene, creosote, lead, formaldehyde, paint thinner

**DISCHARGE PLAN CONSIDERATIONS**

- May need assistance with medical therapies and supplies, self-care activities, and homemaker or home maintenance tasks, transportation, shopping

► Refer to section at end of plan for postdischarge considerations.

- Lethargy, withdrawal, general lack of interest in surroundings

- Self-focusing; guarding behaviors

- Dyspnea, tachypnea
- Dry, nonproductive cough (hilar lymphadenopathy)
- Hoarseness, laryngeal paralysis (pressure from enlarged nodes on the laryngeal nerve)

- Unexplained, intermittent persistent fever without symptoms of infection (HL)
- Generalized pruritus and urticaria (HL)
- Scleral icterus and a generalized jaundice related to liver damage and consequent obstruction of bile ducts by enlarged lymph nodes (may be a late sign)
- Tonsillar or other lymph node enlargement
- Patchy areas of loss of melanin pigmentation (vitiligo)
- Ethroderma (red skin inflamed skin on more than 90% of the body)

## DIAGNOSTIC STUDIES

### TEST

### WHY IT IS DONE

### WHAT IT TELLS ME

## BLOOD TESTS

Blood studies may vary from completely normal to marked abnormalities.

- **Complete blood count (CBC):** Battery of screening tests, which typically includes hemoglobin (Hgb); hematocrit (Hct); RBC count, morphology, indices, and distribution width index; platelet count and size; and WBC count and differential.
- **Differential WBCs:** Percentage of each of the five types of mature WBCs: neutrophils, lymphocytes (B cells and T cells), monocytes, eosinophils, and basophils.
- **Platelets:** Platelets have essential function in coagulation.
- **Erythrocyte sedimentation rate (ESR):** Useful to monitor clients in remission and to detect early evidence of recurrence of disease.
- **Serum lactate dehydrogenase (LDH):** Substance released by tumors; important prognostic indicator in NHL.

*Note:* In stage I, few clients have abnormal blood findings.

RBC production may be decreased due to the lymphoma and suppression of bone marrow activity. Client with HL may have mild to severe normocytic, normochromic anemia associated with hypersplenism. WBCs are variable; that is, they may be normal, decreased, or markedly elevated.

Increased percentage of neutrophils, monocytes, basophils, and eosinophils may be found initially, but these lymphocytes can be profoundly decreased by suppression of marrow activity or by lymphoma treatments. A relative or absolute lymphopenia is a late sign.

Decreased in bone marrow involvement or as a side effect of therapy.

Elevated during active stages and indicates inflammatory or malignant disease.

Elevated; may indicate a more aggressive form of NHL.

## OTHER DIAGNOSTIC STUDIES

- **Chest x-ray:** Determines lung involvement, status of airway, and presence of complications.
- **X-rays or bone scans of thoracic, lumbar vertebrae, proximal extremities, pelvis, or areas of bone tenderness:** Determines areas of involvement and assists in staging.
- **Computed tomography (CT) scans: e.g., head, neck, chest, abdomen, pelvis:** Generally accepted as the primary staging modality for suspected lymphoma and for evaluating therapy response.
- **Positron emission tomography (PET) scan:** Type of nuclear scan that follows course of injected radioactive glucose.
- **Positron emission tomography (PET)-CT scan:** Procedure that combines pictures from both procedures. (Done at the same time on the same machine.)
- **Abdominal ultrasound:** Aids in identifying additional sites and assesses organ status.
- **Biopsies (fine-needle aspiration or excisional)**
- **Bone marrow:** Sampling may be done by needle aspirate or excisional biopsy to determine bone involvement and staging.
- **Cytogenetic analysis:** Cells are studied to see if chromosomal abnormalities are present.
- **Flow cytometry:** Method of counting types of cells with fluorescent tags on the surfaces of the cells.
- **Laparotomy or laparoscopy**

May reveal mediastinal or hilar adenopathy, nodular infiltrates, or pleural effusions.

Bone lesions often associated with acute form of adult T-cell or diffuse large B-cell lymphomas.

Used to assess the extent of disease and responsiveness to therapy. Detects enlarged lymph nodes as well as enlargement of liver and spleen. *Note:* CT scanning of the head and/or neck is mandatory for client with head and neck presentation or symptoms of cranial neuropathies such as hearing loss, vertigo, or visual changes (Dunleavy et al, 2017). Most people have repeated CT scans to monitor the status of their disease or evaluate for recurrence.

Malignant cells take up more glucose than normal cells. Thus, PET scanning identifies hypermetabolic areas that suggest malignancy and assists with staging of the disease. *Note:* Combined images from PET-CT scans provide a more detailed picture than either test would make by itself.

Evaluates extent of involvement of retroperitoneal lymph nodes and determines size of kidneys and patency of urinary tract in preparation for chemotherapy.

Establishes diagnosis and cell type involved. *Note:* Presence of Reed-Sternberg cells from blood and lymph cells confirms diagnosis of HL (Foster & Prevost, 2012).

Detects different types of chromosome aberrations and can be used to plan treatment and measure the results of treatment. Often used to determine the type of lymphoma cells present. For example, each disease subtype has a specific pattern of markers on its cell surface.

For some of the more aggressive types of lymphoma, this test can sometimes detect residual disease long before it grows large enough to be detected by any other means.

Procedures may be done to examine organs inside abdomen for signs of disease and to obtain tissue samples for cytology.

**NURSING PRIORITIES**

1. Provide physical and psychological support during extensive diagnostic testing and treatment regimen.
2. Prevent complications.
3. Alleviate pain.
4. Provide information about disease process, prognosis, and treatment needs.

**DISCHARGE GOALS**

1. Complications prevented or minimized.
2. Individual situation dealt with realistically.
3. Pain relieved or controlled.
4. Disease process, prognosis, possible complications, and therapeutic regimen understood.
5. Plan in place to meet needs after discharge.

**\*\*\*Refer to CPs: Cancer: General Considerations for shared related nursing diagnoses such as Pain, Fatigue, Nausea, Nutrition, Anxiety, Self-Esteem and Grieving, to accomplish corresponding nursing priorities and discharge goals.**

**See also other related cancer care plans for nursing interventions related to treatments such as radiation, chemotherapy, and bone marrow transplant.**

**NURSING DIAGNOSIS:** risk for impaired Gas Exchange**Possibly Evidenced By**

[Altered oxygen-carrying capacity of blood]

[Tracheobronchial obstruction (disease invasion: enlarged mediastinal nodes and airway edema (HL and NHL), superior vena cava syndrome (NHL)]

**Desired Outcomes/Evaluation Criteria—Client Will****Respiratory Status: Ventilation NOC**

Maintain a normal, effective respiratory pattern, free of dyspnea, cyanosis, or other signs of respiratory distress, and arterial blood gases (ABGs) within normal limits (WNL).

**ACTIONS/INTERVENTIONS****RATIONALE****Ventilation Assistance NIC****Independent**

Ascertain presence of lymphoma affecting head and neck; determine client's particular disease condition, stage, and severity of lymphoma and treatment status (e.g., post-surgery, in chemotherapy, or experiencing late and long-lasting treatment side effects).

Aids in establishing baseline respiratory status and can point to potential cause and needed interventions if client is having difficulty breathing. For example, symptoms may be associated with late-stage primary lymphoma of head or neck (not easily treated). Conversely, client might be in the immediate postoperative phase for throat and neck surgery with tissue and airway edema (more easily treated condition). Also, chemotherapies, radiation, or splenectomy render the client more prone to lung infections and lung damage. While both conditions can lead to shortness of breath, lung damage is much more likely to present poor prognosis. Note: It has been established that lymphoma is the second most common primary malignancy occurring in the head and neck (Dunleavy et al., 2017).

Assess and monitor respiratory rate, depth, and rhythm.

Note reports of dyspnea or use of accessory muscles, nasal flaring, and altered chest excursion.

Changes (e.g., tachypnea, dyspnea, and use of accessory muscles) may indicate progression of disease- or treatment-related respiratory involvement, requiring prompt intervention.

Place client in position of comfort, usually with head of bed elevated or sitting upright, leaning forward with weight supported on arms, and feet dangling.

Maximizes lung expansion, decreases work of breathing, and reduces risk of aspiration.

Reposition and assist with turning periodically.

Promotes aeration of all lung segments and mobilizes secretions.

Instruct in and assist with deep-breathing techniques and pursed-lip or abdominal diaphragmatic breathing, if indicated.

Helps promote gas diffusion and expansion of small airways. Provides client with some control over respiration, helping to reduce anxiety.

(continues on page 588)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Evaluate skin color, noting pallor or development of cyanosis, particularly in nailbeds, ear lobes, and lips.	Proliferation of WBCs and anemia can reduce oxygen-carrying capacity of the blood, leading to systemic hypoxemia.
Assess respiratory response to activity. Note reports of dyspnea and increased fatigue. Schedule rest periods between activities.	Decreased cellular oxygenation reduces activity tolerance. Rest reduces oxygen demands and minimizes fatigue and dyspnea.
Encourage energy-saving techniques, such as rest periods before and after meals, use of shower chair, and sitting for care.	Aids in reducing fatigue and dyspnea and conserves energy for cellular regeneration and respiratory function.
Promote bedrest and provide care as indicated during acute or prolonged exacerbation.	Worsening respiratory involvement and hypoxia may necessitate cessation of activity to prevent more serious respiratory compromise.
Encourage expression of feelings. Acknowledge reality of situation and normality of feelings.	Anxiety increases oxygen demand, and hypoxemia potentiates respiratory distress or cardiac symptoms, which in turn escalates anxiety.
Provide calm, quiet environment.	Promotes relaxation, conserving energy and reducing oxygen demand.
Observe for neck vein distention, headache, dizziness, periorbital or facial edema, dyspnea, and stridor.	NHL client is at risk for superior vena cava syndrome (SVC) when lymphoma has invaded the mediastinum, which can result in tracheal deviation and airway obstruction, an oncological emergency.
Provide support to family and SOs.	Development of SVC is very frightening for client and family because it may indicate the end stage of disease process. Keeping family informed may diminish their anxiety and minimize transmission to client.
<b>Collaborative</b>	
Assist with treatment of disease process and side effects of therapies.	Interventions to correct or manage anemia can improve oxygenation.
Provide supplemental oxygen by appropriate route.	Maximizes oxygen available for circulatory uptake, aids in reducing hypoxemia improving tolerance of activity, especially in the setting of severe anemia, cardio-pulmonary or renal complications.
Monitor laboratory studies, such as ABGs and pulse oximetry.	Measures adequacy of respiratory function and effectiveness of therapy.
Administer analgesics and tranquilizers, as indicated.	Reducing physiological responses to pain and anxiety decreases oxygen demands and may limit respiratory compromise.
Assist with respiratory treatments and adjuncts, such as intermittent positive-pressure breathing (IPPB) and incentive spirometer, if appropriate.	Promotes maximal aeration of all lung segments, preventing atelectasis.
Assist with intubation and mechanical ventilation.	May be necessary to support respiratory function until airway edema is resolved in acutely ill hospitalized client.
Prepare for other procedures—thrombolysis, emergency radiation, endovascular stenting, or thoracentesis when indicated.	SVC rarely presents as an acute emergency, but when it does, life-saving treatments must be immediately carried out.

## NURSING DIAGNOSIS: acute/chronic Pain

### May Be Related To

Physical injury agents—[neoplasm of lymphoid tissue; disease invasion of organs]; nerve compression, ischemia; [treatment-related damage to peripheral nerves]

Chemical injury agents—chemotherapy

Alteration in sleep pattern, anxiety, fear

**NURSING DIAGNOSIS:** **acute/chronic Pain** (continued)**Possibly Evidenced By**

Self-report of pain intensity and characteristics using a standardized scale  
 Guarding behaviors  
 Expressive behaviors—facial grimacing, restlessness  
 Changes in vital signs (acute pain)

**Desired Outcomes/Evaluation Criteria—Client Will****Pain Level NOC**

Report pain is relieved or controlled.  
 Appear relaxed and able to sleep and rest appropriately.

**Pain Control NOC**

Demonstrate behaviors to manage pain.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Pain Management: Acute/Chronic NIC</b>	
<b>Independent</b>	
Identify contributing factors (i.e., diagnosed lymphoma of one or body systems, late-stage disease, side effects of cancer therapies).	Pain associated with lymphomas is often twofold: (1) primary pain is caused by the cancer itself. Many NHL patients experience bone and/or nerve pain. And, since the disease may develop in many parts of the body—such as the neck, groin, breastbone, and underarm—pain varies for each individual. (2) Secondary pain may result from common cancer treatments such as chemotherapy, radiation therapy, and surgery. For example, chemotherapy may lead to peripheral neuropathy, a condition that causes tingling, numbness, and weakness in the hands and arms or legs and feet.
Investigate reports of pain. Note changes in intensity, character, and location of pain.	Pain with lymphomas may be (1) acute (depending on stage of disease and organs involved), (2) chronic (and acute superimposed upon chronic), and (3) breakthrough (triggered by a particular activity or change in medications) in a client already on pain management measures.
Monitor vital signs, noting changes in blood pressure, heart rate, and breathing pattern. Note nonverbal cues, such as facial mask of pain, grimacing, crying, withdrawal, muscle tension, and restlessness.	Indicators of acute pain that can corroborate verbal reports or may be only indicators in client unable or unwilling to verbalize pain. Client with long-term condition may have acute pain superimposed on chronic pain issues and be reluctant to report new symptoms. Older client may or may not report pain but may have more pain behaviors.
Determine client's acceptable level of pain and help client achieve pain control.	Pain is a subjective experience and needs to be fully addressed by care providers to promote the best possible quality of life. Client may report having a level of discomfort that is manageable (e.g., can do desired activities when pain level is reduced from a 10 to a 3). Another client may need to be pain-free in order to function.
Provide quiet environment and reduce stressful stimuli: noise, lighting, and constant interruptions.	Promotes rest and enhances coping abilities.
Provide comfort measures, such as massage, cool packs, and psychological support, including encouragement and presence, as appropriate.	Nonpharmacologic measures can enhance effects of medication.
Review and promote client's own comfort interventions—position and physical activity or nonactivity.	Successful management of pain requires client involvement. Use of effective techniques provides positive reinforcement, promotes sense of control, and prepares client for interventions to be used after discharge.
Evaluate and support client's coping mechanisms.	Using own learned perceptions and behaviors to manage pain can help client cope more effectively.

(continues on page 590)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Encourage use of stress management techniques, such as deep-breathing exercises, guided imagery, visualization, and Therapeutic Touch.	Facilitates relaxation, augments pharmacological therapy, and enhances coping abilities.
Assist with or provide diversional activities and relaxation techniques.	Helps with pain management by redirecting attention.
<b>Collaborative</b> Collaborate in treatment of underlying condition(s) and protocols for management of treatment side effects.	***Note: There is no one-size-fits-all treatment plan for lymphomas, because while there are similarities in lymphomas, they are also unique to the individual and subtype of the disease. Therefore, treatments are highly individualized. Thus, nurse is referred to physician treatment plan for each individual and pharmacologic/medical resources for information regarding treatment types and related concerns for each one.
Administer other medications, as indicated, for example:	
Analgesics, such as acetaminophen (Tylenol), and NSAIDs ( <i>including and not limited to</i> ) motrin (Advil), naproxen (Naprosyn), and ketorolac (Toradol)	Given for mild to moderate acute and chronic pain not relieved by comfort measures. Note: Avoid aspirin-containing products because they may potentiate hemorrhage.
Opioids ( <i>including and not limited to</i> ) (1) codeine, morphine, and hydromorphone (Dilaudid) and (2) fentanyl (Duragesic), hydrocodone (Vicodin), and oxycodone (Oxycontin)	Opioids may be used for acute and chronic pain. Typically, those in list 1 are used to manage disease-related organ pain and breakthrough pain. Drugs in list 2 are often needed to manage the chronic pain syndromes often associated with lymphomas.
Antianxiety agents, such as diazepam (Valium) and lorazepam (Ativan)	May be given to enhance the action of analgesics and opioids.

## NURSING DIAGNOSIS: Nausea

### May Be Related To

Treatment regimen [chemotherapeutic agents; radiation therapy]  
Gastrointestinal irritation

### Possibly Evidenced By

Gagging sensation  
Aversion toward food

### Desired Outcomes/Evaluation Criteria—Client Will

#### Nausea & Vomiting Severity NOC

Be free of nausea.

#### Nausea & Vomiting Disruptive Effects NOC

Manage nausea as evidenced by acceptable level of dietary intake.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Nausea Management NIC</b> <i>Independent</i> Identify client at risk for nausea and vomiting (e.g., receiving chemotherapy treating, presence of localized GI disease, pain).	Nausea is associated with both the lymphoma condition and treatment, which can result in severe discomfort, malnutrition, and fluid deficits. Note: Chemotherapy-induced nausea and vomiting (CINV) is one of the most feared side effects of chemotherapy. With the correct use of antiemetics, CINV can be prevented in 70% to 80% of patients (Jordan et al, 2014; NCI, 2017a).
Assess/document the presence and severity of nausea ongoing.	Helps identify therapy needs and response to interventions.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Control environmental factors, such as strong or noxious odors or noise. Avoid overly sweet, fatty, or spicy foods.	Can trigger nausea and vomiting response.
Encourage use of relaxation techniques, such as visualization, guided imagery, and moderate exercise before meals.	May prevent onset or reduce severity of nausea, decrease anorexia, and enable client to increase oral intake.
Provide or encourage frequent oral hygiene.	Prevents drying of mucosa, promotes comfort, and reduces sour taste sometimes associated with cancer therapies.
Evaluate effectiveness of antiemetic agents.	Individuals respond differently to all medications. First-line antiemetics may not work, requiring alteration in or use of combination drug therapy.
Identify client who experiences anticipatory nausea or vomiting and take appropriate measures.	Psychogenic nausea and vomiting occurring before chemotherapy generally does not respond to antiemetic drugs. Change of treatment environment or client routine on treatment day may be effective.
Encourage open communication regarding anorexia.	Often a source of emotional distress, especially for SO who wants to feed client frequently. When client refuses, SO may feel rejected or frustrated.
Adjust diet before and immediately after treatment (such as providing clear, cool liquids; light or bland foods; dry crackers; toast), as indicated.	The effectiveness of diet adjustment is individualized in relief of posttherapy nausea. Clients must experiment to find best solution.
<b>Collaborative</b> Refer to other healthcare providers and services as indicated.	Assistance may be needed over time from various experienced providers (e.g., nutritionist/dietary services, oncology physician, nurse, and pharmacist) who provide advice and a comprehensive coordinated approach to treating cancer-associated nausea.
Administer medications, as indicated, for example:	Antiemetics may be given prophylactically or on a regular schedule during and after treatments. Note: Relieving nausea and vomiting can reduce fluid deficits, enhance oral intake, and greatly improve client's quality of life.
Antiemetics: such as ondansetron (Zofran), inapsine (Droperidol), aprepitant (Emend), and dronabinol (Marinol)	Most antiemetics act to interfere with stimulation of the vomiting center in the brain, and chemoreceptor trigger zone agents also act peripherally to inhibit reverse peristalsis.
Antacids and proton pump inhibitors, such as esomeprazole (Nexium), lansoprazole (Prevacid), and pantoprazole (Protonix)	Minimizes gastric irritation, decreases nausea, and reduces risk of mucosal ulceration. Note: Client with <i>H. pylori</i> gastritis is at increased risk for lymphoma; therefore, it is conceivable that client with lymphoma may have gastritis or ulcers associated with <i>H. pylori</i> .

## NURSING DIAGNOSIS: Sexual Dysfunction

### May Be Related To

Altered body structure or function (e.g., disease process, surgery, chemotherapy, radiation)

### Possibly Evidenced By

Alteration in sexual activity/satisfaction

Actual or perceived limitations

Insufficient knowledge/misinformation about sexual function

[Change in relationship with SO]

### Desired Outcomes/Evaluation Criteria—Client Will

#### Sexual Functioning NOC

Verbalize understanding of individual reasons for sexual problems.

Identify stressors in lifestyle that may contribute to the dysfunction.

Discuss concerns about body image, sex role, and desirability as a sexual partner with partner or SO.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Sexual Counseling NIC</b>	
<b>Independent</b>	
Assess knowledge of client and SO regarding sexual function and effects of current situation.	Lymphomas often affect the relatively young in their reproductive years, who may be less knowledgeable about the possibilities of change.
Collaborate with other healthcare team members in informing client and partner of potential sexual side effects of treatment plans and provide opportunity to consider options. Discuss sperm banking and pregnancy issues, when appropriate, before beginning treatment.	Some lymphomas and the treatments used for them can affect male and female sexual development, libido, fertility, and the success of pregnancy. In males, impotence and permanent sterility can occur as a result of radiation when combined with certain chemotherapeutic agents. In females, menstruation may cease during the active phase of treatment, and infertility may occur. The woman's age during treatment and certain chemotherapy regimens (e.g., type and dose of alkylating agent) are more likely than others to impact fertility. In addition, side effects of treatment can impact sexual enjoyment (e.g., vaginal dryness and atrophy of vaginal tissues) but can be managed when client and partner are given information and resources (Harel et al, 2010; Recklitis et al, 2010).
Identify preexisting and current stress factors that may be affecting the relationship.	Client may be concerned about other issues, such as job, financial, and illness-related problems.
Determine specific pathophysiology involved and impact on, or perception of, individual.	Client's perception of the individual effects of this illness is crucial to planning interventions that will be appropriate to those affected.
Assist with treatment of underlying condition.	As illness is treated and client can see improvement, hope is restored and client can begin to look to the future.
Provide factual information.	Promotes trust in caregivers.
Encourage and accept expressions of concern, anger, grief, and fear.	Helps client identify feelings and begin to deal with them.
Encourage client to share thoughts and concerns with partner and to clarify values and impact of condition on relationship.	Helps couple begin to deal with issues that can strengthen or weaken relationship.
<b>Collaborative</b>	
Refer to appropriate community resources or support groups for sexual dysfunction, such as the American Cancer Society.	Provides information about resources that are available to help with individual needs. Meeting with others who are dealing with the effects of devastating illness can help client and family.
Provide written material, informational websites such as Fertile Hope, and other resources appropriate to age and situation.	Reinforces information client has received regarding sexual and fertility issues.
Refer to psychiatric clinical nurse specialist or professional sexual therapist, as indicated.	May need additional in-depth assistance to resolve existing problems.

**NURSING DIAGNOSIS:** **deficient Knowledge regarding disease process, prognosis, treatment regimen, self-care, and discharge needs**

**May Be Related To**

Lack of exposure, recall  
Insufficient information; misinformation presented by others  
Insufficient knowledge of resources  
Alteration in cognitive functioning

**Possibly Evidenced By**

Insufficient knowledge  
Inaccurate follow-through of instruction

<b>NURSING DIAGNOSIS:</b> <b>deficient Knowledge regarding disease process, prognosis, treatment regimen, self-care, and discharge needs</b> (continued)	
<b>Desired Outcomes/Evaluation Criteria—Client Will</b>	
<b>Knowledge: Cancer Management NOC</b>	
ACTIONS/INTERVENTIONS	RATIONALE
<b>Teaching: Disease Process NIC</b>	
<i>Independent</i>	
Review with client and SO their understanding of client's diagnosis and outlook.	Although lymphomas are complex and have intensive treatment regimens, the outlook has improved in recent years. The 5-year survival rate after treatment in both categories of lymphomas has improved significantly, and many people live with lymphoma in remission.
Review potential treatments client may be considering.	May assist client and SO in making informed choices. Note: In general, the goal of therapy is remission of the lymphoma, and treatments vary according to the disease process and stage.
Various combinations of chemotherapy agents and/or radiation therapy	Chemotherapy and radiation therapy are the most commonly used treatments and may be used alone or combined. Chemotherapy is a systemic treatment that uses a combination of several drugs, given by IV injection or by mouth, typically given in cycles, based on the duration of the drug's effect and other factors. Radiation therapy targets and kills cancer cells in a specific area, using an external beam (EBRT) or radioisotope-targeted therapy (see below). Since lymphoma cells are likely to be present in widespread areas, radiation therapy is not commonly used alone.
Interferon-alpha (INF- $\alpha$ ) and monoclonal antibodies, such as rituximab (Rituxan) and alemtuzumab (Campath)	Biological therapies may be used to treat HL or NHL.
Targeted therapies such as:	In this therapy, radioisotopes are attached to monoclonal antibodies and delivered intravenously to target and destroy specific cancer cells. By delivering the radiation directly to the tumor cells, this treatment helps limit toxic effects on normal tissues.
Stem cell transplantation	Stem cell transplant from bone marrow is now standard therapy for selected clients with NHL. May be combined with high-dose chemotherapy for clients with HL who have relapsed or who have experienced a failed primary chemotherapy regimen.
Discuss potential complications relative to specific therapeutic regimen.	Receiving radiation or chemotherapy increases the risk of contracting another type of lymphoma or another type of cancer, so client will continue to need monitoring after treatment. After 5 disease-free years, however, risk becomes close to normal.
Emphasize need for ongoing medical follow-up, posttreatment surveillance, and testing.	After completion of primary therapy, appropriate tests will be repeated to determine efficacy of therapy. Also, monitoring for certain late or long-term side effects of HL treatment (e.g., fertility issues, infections, thyroid dysfunction) are continued (ACS, 2017c).

(continues on page 594)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Identify signs and symptoms requiring further evaluation, such as cough, fever, chills, malaise, dyspnea, weight gain, slow pulse, decreased energy level, intolerance to cold; moderate fever, chest pain, dry cough, dyspnea, rapid pulse (pericarditis [rare]); or dyspnea, fatigue, chest pain, dizziness, or syncope (cardiomyopathy [rare]).	Prompt intervention can identify recurrence or perhaps limit progression of complications, thereby reducing further debilitating effects.
Recommend regular exercise in moderation, with adequate rest. Discuss energy conservation techniques. Refer for physical therapy or cancer exercise program, as indicated.	Promotes general well-being. Note: Fatigue is associated with disease process and treatment regimen as well as developing complications. Therefore, balancing activity with rest enhances client's ability to perform activities of daily living (ADLs).
Recommend or refer to appropriate community resources—support groups, social worker, counselor, pastor; home health assistance, medical equipment and supplies; hospice; and Lymphoma Research Foundation and American Cancer Society.	Client and SO can benefit from many available resources and networks for such help as care assistance, transportation to treatments, sources of financial resources, and long-term support or counseling.

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

- **ineffective Health Management**—complexity of therapeutic regimen, decisional conflicts, economic difficulties, excessive demands made on individual or family, perceived benefits, powerlessness
- **risk for Infection**—inadequate secondary defenses: alterations in mature WBCs (low granulocyte and abnormal lymphocyte count), increased number of immature lymphocytes, immunosuppression, bone marrow suppression (effects of therapy/transplant)
- **ineffective Role Performance**—situational crisis, physical illness, fatigue, stress
- **interrupted Family Processes**—situational crisis (illness, disabling and expensive treatments); shift in health status of a family member, shift in family roles

# Renal and Urinary Tract Disorders

## ACUTE KIDNEY INJURY (ACUTE RENAL FAILURE)

### I. Pathophysiology

Acute kidney injury (AKI) has been defined as a sudden decrease in kidney function that happens within a few hours or few days, which may or may not be associated with a decrease in urine output, and is usually marked by a rise in serum creatinine concentration or by azotemia (a rise in blood urea nitrogen [BUN] concentration). The term *acute renal failure* is used when the kidney injury results in the need for renal replacement therapies (RRT), including (but not limited to) intermittent hemodialysis.

### II. Stages and Phases (Dirkes, 2015; Palevsky, 2017)

Several classifications have been used over time to describe kidney failure. In recent years, more work has been applied to defining and classifying acute kidney injury (formerly called acute renal failure) including:

- a. In 2012, the Kidney Disease Improving Global Outcomes (KDIGO) work group released clinical practice guidelines for AKI to improve definition and staging criteria. These define AKI as **any** of the following:
  - i. Increase in serum creatinine by 0.3 mg/dL or more within 48 hours, **OR**
  - ii. Increase in serum creatinine to 2.5 times baseline or more within the last 7 days, **OR**
  - iii. Urine output less than 0.5 mL/kg/h for 6 hours (Acute Kidney Injury Work Group, 2012).
- b. AKI has four phases, described as:
  - i. Onset: has a triggering event, renal blood flow is diminished; lasts hours to days
  - ii. Oliguric/anuric: BUN and creatinine (Cr) are elevated; electrolyte and acid base disturbances present; may last 8 to 14 days (or longer), depending on cause and renal replacement therapies.
  - iii. Diuretic: occurs as AKI is corrected; increased glomerular filtration rate (GFR); typically lasts 1 to 2 weeks
  - iv. Recovery: normalization of fluid and electrolyte imbalances. GFR returns to 70% to 80% of normal; lasts several months to a year.
- c. Urine output phases are described as anuria, oliguria, and nonoliguria and can point to causes of AKI. *Note:* Approximately 50% to 60% of all causes of AKI are nonoliguric (Workeneh et al, 2017).
  - i. Anuria (<100 mL/d): may be associated with such conditions as urinary tract obstruction, renal artery

obstruction, rapidly progressive glomerulonephritis, and bilateral diffuse renal cortical necrosis

- ii. Oliguria (100–400 mL/d): may be associated with conditions such as prerenal failure and hepatorenal syndrome
- iii. Nonoliguria (>400 mL/d): may be associated with conditions such as acute interstitial nephritis, acute glomerulonephritis, partial obstructive nephropathy, nephrotoxic and ischemic acute tubular necrosis (ATN), radiocontrast-induced AKI, and rhabdomyolysis

### III. Etiology (National Kidney Foundation, 2017; Workeneh et al, 2017)

- a. Multiple causes include conditions causing decreased blood flow (prerenal), diseases or conditions causing direct damage to kidney (intrarenal), and blockage of structures of the urinary tract (postrenal).
  - i. Prerenal failure: blood volume depletion due to hemorrhage, “third-space” sequestration of fluid as in edema or ascites in advanced liver disease, or burns; dehydration due to gastrointestinal (GI) losses or overuse of diuretics; septic or anaphylactic shock; heart failure (HF) with renal insufficiency, myocardial infarction (MI), trauma; renal artery obstruction; and certain nephrotoxic drugs, such as nonsteroidal anti-inflammatory drugs (NSAIDs), cyclooxygenase inhibitors, angiotensin-converting enzyme (ACE) inhibitors; synthetic cannabinoids (SCs).
  - ii. Intrarenal (intrinsic) failure: resulting from direct injury with structural and functional damage to kidney from ischemia, hypoperfusion, and primary kidney disease. Can be caused by infections (*Note:* Sepsis is one of the most common causes of AKI); blood transfusion reaction, renal artery stenosis; and direct damage from nephrotoxic substances, such as radiocontrast media, cyclosporine, heavy metals (e.g., lead, mercury), cytotoxic drugs (e.g., certain chemotherapy agents), and certain antibiotics (e.g., carbamiphenilins, aminoglycosides).
  - iii. Postrenal failure: most commonly occurs with stones in the ureters, bladder, or urethra; from trauma or edema associated with infection, prostatic hypertrophy, or cancer; cervical cancer; strictures of renal artery

(continues on page 596)

**II. Risk factors**—While there are many risk factors, the older client (75 or older) is at particular risk. This may be due to age-related structural and functional changes in the kidney; comorbid conditions (e.g., diabetes, hypertension, influenza, sepsis, heart or liver failure), polypharmacy (including a variety of nephrotoxic drugs) and an increase in hospitalizations, and high-risk medical and surgical procedures (Thornburg & Gray-Vickrey, 2016; Workeneh et al, 2017).

**III. Statistics**

- a. Morbidity: Infections commonly complicate the course of AKI and have been reported to occur in as many as 33% of patients with AKI. Neurologic signs of uremia are a common complication of AKI and have been reported in approximately 38% of patients with AKI (Workeneh et al,

2017). In one study, survivors of severe AKI had an unfavorable health-related quality of life (mentally and physically) compared with general population (Wang et al, 2015).

- b. Mortality: One recent study revealed that while acute kidney injury requiring dialysis (AKI-D) admissions are on the rise, hospital mortality for AKI-D has declined significantly between 2001 and 2011 (Brown et al, 2016).
- c. Costs: A recent study based on 2012 figures found that AKI in the United States was associated with increased hospitalization costs of \$7933 per patient/per day compared to patients without AKI and that costs were comparable to those for stroke, pancreatitis, and pneumonia (Zeng et al, 2014).

## G L O S S A R Y

**Acute tubular necrosis (ATN):** Structural injury or tissue necrosis within the kidney, caused by ischemia or toxic injury. Necrosis is usually patchy, but injury can be widespread. ATN should be suspected in any individual presenting after a period of hypotension secondary to cardiac arrest, hemorrhage, sepsis, drug overdose, or surgery.

**Anuria:** Urine output less than 100 mL/d.

**Azotemia:** Buildup of nitrogenous waste products, specifically urea, in the blood.

**Calculus:** Mass of solid material or metabolic substance—kidney or bladder stone.

**Catabolic:** Destructive metabolism, or breakdown, of proteins for energy results in muscle wasting, loss of lean muscle mass, and negative nitrogen balance.

**Glomerular filtration rate (GFR):** Rate of fluid filtration through the kidney glomeruli.

**Glomerulonephritis:** Inflammation of the glomerular capillary walls, causing impaired filtration.

**Hydronephrosis:** Kidney enlargement caused by urine backing up from the bladder into the kidney or inability of urine to drain from the kidney into bladder; excessive reflux stretches the kidney, causing functional damage to it.

**Myoglobin:** Form of hemoglobin found in muscle tissue and released into urine when tissue damage occurs.

**Nephrotoxins:** Chemical substances, including medications that can cause kidney damage.

**Nonoliguric AKI:** Urinary output more than 400 mL/d.

**Oliguria:** Urinary output less than 400 mL/d.

**Orthostatic hypotension:** Decrease in blood pressure when person rises from seated or lying position; often associated with hypovolemia.

**Parenchymal disease:** Connective tissue of the kidney is damaged and scarred.

**Polyuria:** Excretion of large amounts (2–6 L/24 hr) of urine, lacking concentration and regulation of waste products; occurs during diuretic phase of AKI, with head injury (diabetes insipidus [DI]) and diabetic ketoacidosis (DKA).

**Porphyrins:** Nitrogen-containing chemical components of hemoglobin.

**Pyelonephritis:** Infection of the kidney's medulla or cortex.

**Renal replacement therapy (RRT):** Umbrella term used for life-saving treatments for renal failure, including hemodialysis, peritoneal dialysis, hemofiltration, and renal transplantation.

**Uremia:** Toxic clinical syndrome associated with fluid, electrolyte, and hormone imbalances and metabolic abnormalities due to deterioration of renal function and the deleterious effects of azotemia on organ systems.

## CARE SETTING

Client will be treated in inpatient acute medical, surgical, or intensive care unit.

## RELATED CONCERNs

Fluid and electrolyte imbalances (see *DavisPlus*)  
Metabolic acidosis—primary base bicarbonate deficiency (see *DavisPlus*)

Psychosocial aspects of care, page 835

Renal dialysis—general considerations, page 623

Chronic kidney disease with end stage renal failure, page 607

Sepsis/septicemia, page 772

Total nutritional support: parenteral/enteral feeding, page 525

Upper gastrointestinal bleeding, page 340

**CLIENT ASSESSMENT DATABASE****DIAGNOSTIC DIVISION  
MAY REPORT****MAY EXHIBIT****ACTIVITY/REST**

- Fatigue, weakness, malaise

**CIRCULATION**

- Muscle weakness, loss of tone
- Hypotension or hypertension, including accelerated (malignant) hypertension, eclampsia, or gestational hypertension
- Cardiac dysrhythmias associated with hyperkalemia and hypocalcemia
- Weak, thready pulses; orthostatic hypotension (hypovolemia)
- Jugular vein distention (JVD), full and bounding pulses (hypervolemia)
- Generalized tissue edema, including periorbital area, ankles, sacrum
- Pallor (anemia); bleeding tendencies

**ELIMINATION**

- Change in usual urination pattern—increased frequency (early failure and early recovery) or decreased frequency or oliguria (later phase)
- Dysuria, hesitancy, urgency, and retention (obstruction or infection)
- Abdominal bloating, diarrhea, or constipation
- History of benign prostatic hyperplasia (BPH) or kidney or bladder stones

- Change in urinary color; for example, ranges from absence of color to deep yellow, reddish-brown, and cloudy
- Oliguria: Production of a small amount of urine with no other indicators (e.g., presence of stones or prostate enlargement) generally favors AKI. A gradually diminishing urine output may indicate a urethral stricture or bladder outlet obstruction due to prostate enlargement.
- Polyuria: occurs during diuretic phase of AKI, with head injury (diabetes insipidus [DI]) and diabetic ketoacidosis (DKA).
- Anuria: Abrupt anuria suggests acute urinary obstruction, acute and severe glomerulonephritis, or embolic renal artery occlusion (Workeneh et al, 2017).

**FOOD/FLUID**

- Nausea, anorexia, heartburn
- Vomiting
- Weight gain (edema), weight loss (dehydration)
- Use of diuretics

- Changes in skin turgor and moisture
- Edema—generalized, dependent

**NEUROSENSORY**

- Headache, blurred vision
- Muscle cramps or twitching, “restless leg” syndrome, numbness, tingling

- Altered mental state—decreased attention span, inability to concentrate, loss of memory, confusion, decreasing level of consciousness (LOC) (azotemia, electrolyte and acid-base imbalance)
- Twitching, muscle fasciculation, seizure activity

**PAIN/DISCOMFORT**

- Flank pain, headache

- Guarding or distraction behaviors, restlessness

**RESPIRATION**

- Shortness of breath

- Tachypnea, dyspnea, increased rate and depth; Kussmaul’s respiration can be compensatory mechanism because of metabolic acidosis.
- Cough productive of pink-tinged sputum (pulmonary edema)

**SAFETY**

- Recent transfusion reaction
- Current or recent hospitalization (*Note:* Most community-acquired AKI is secondary to volume depletion; as many as 90% of cases are estimated to have a potentially reversible cause) (Sinert & Peacock, 2015)

- Fever (sepsis, dehydration)
- Petechiae, ecchymotic areas on skin
- Pruritus, dry skin

(continues on page 598)

**TEACHING/LEARNING**

- Family history of polycystic disease, hereditary nephritis, urinary calculus, malignancy
- History of exposure to toxins, such as drugs (cyclosporine, amphotericin B, cocaine), environmental poisons (e.g., ethyl alcohol, ethylene glycol, mercury vapors, lead, cadmium, or other heavy metals), substance abuse
- Current or recent use of nephrotoxic drugs, such as aminoglycoside antibiotics, amphotericin B; anesthetics; ACE inhibitors and vasodilators; NSAIDs such as ibuprofen, naproxen
- Recent diagnostic testing with radiographic contrast media reaction
- Concurrent conditions—tumors in the urinary tract, gram-negative sepsis, trauma or crush injuries, hemorrhage, disseminated intravascular coagulation (DIC), burns, electrocution injury, autoimmune disorders (e.g., scleroderma, vasculitis), vascular occlusion or surgery, diabetes mellitus (DM), cardiac or liver failure

**DISCHARGE PLAN CONSIDERATIONS**

- May require alteration or assistance with medications, treatments, supplies, transportation, and homemaker or maintenance tasks

♦ Refer to section at end of plan for postdischarge considerations.

**DIAGNOSTIC STUDIES****TEST  
WHY IT IS DONE****WHAT IT TELLS ME****BLOOD TESTS*****Kidney function studies:***

- **Blood urea nitrogen (BUN):** Measures the by-product of protein metabolism in the liver, filtered by the kidneys and excreted in urine.
- **Creatinine (Cr):** End product of muscle and protein metabolism filtered by the kidneys and excreted in urine.
- **BUN/Cr ratio:** Ratio helps determine whether factors other than kidney failure are causing changes in the levels. Normal ratio is 10:1.

*Note:* BUN, Cr, GFR, and urine output have long been standard tests for assessing renal function. But recent research shows BUN and creatinine tests don't reflect real-time kidney function or accurately reflect the GFR or degree of tubular injury. Recently, the emphasis has been shifting from biomarkers indicating kidney failure to those that signal a change in kidney function.

Elevated BUN is highly suggestive of kidney dysfunction. *Note:* Although BUN can be affected by many factors, including drug therapy, nutritional status (including high protein intake), GI bleeding, trauma, and infection, and because BUN takes up to 24 hours to rise, it doesn't indicate when kidney injury occurred. AKI presents clinically as a rapidly rising creatinine (Cr) over several hours or days. *Note:* Serum creatinine level is affected by the person's muscle mass, age, race, and gender. Also, it may not rise for 12 to 24 hours after kidney injury. In normal individuals and in client with intrinsic renal disease, the BUN will be approximately 10 times that of Cr. Therefore, a BUN/Cr ratio considerably greater than 10 suggests a prerenal (decreased renal perfusion) or postrenal (obstruction) cause of renal failure.

WHY IT IS DONE (continued)	WHAT IT TELLS ME (continued)
<ul style="list-style-type: none"> <li><b>AKI biomarkers (e.g., cystatin C, kidney injury molecule 1 [KIM-1], neutrophil gelatinase-associated lipocalin [NGAL], interleukin-18 [IL-18])</b></li> <li><b>Complete blood count (CBC):</b> Battery of screening tests, which typically includes hemoglobin (Hgb); hematocrit (Hct); red blood cell (RBC) count, morphology, indices, and distribution width index; platelet count and size; and white blood cell (WBC) count and differential.</li> <li><b>Arterial blood gases (ABGs):</b> Determines the pH and the percentage of oxygen, carbon dioxide, and bicarbonate in arterial blood.</li> <li><b>Electrolytes or renalytes:</b> Electrically charged minerals found in body tissues and blood in the form of dissolved salts. They help move nutrients into and wastes out of the body's cells, maintain water balance, and stabilize the body's pH level.</li> <li><b>Serum osmolality:</b> Measures the amount of chemicals dissolved in the serum. Kidneys excrete or reabsorb water to keep osmolality in range of 280 to 300 mOsm/kg. Chemicals that affect serum osmolality include sodium, chloride, bicarbonate, protein, and glucose.</li> </ul>	<p>Research is currently being conducted regarding use of new biomarkers for more accurate, real-time indicators of AKI and need for renal replacement therapies (Dirkes, 2015; Siew et al, 2011).</p> <p>Hgb is decreased in presence of acute blood loss or chronic anemia, which is the main hematologic effect of AKI. RBCs are often decreased because of increased fragility and decreased survival time. Elevated WBC count (leukocytosis) can point to infection (such as sepsis) as a cause of AKI (Workeneh et al, 2017).</p> <p>Metabolic acidosis (pH less than 7.2) may develop because of decreased renal ability to excrete hydrogen and end products of metabolism. Bicarbonate is decreased.</p> <p>Sodium—usually increased but may vary.</p> <p>Potassium—elevated related to retention and cellular shifts (acidosis) or RBC hemolysis.</p> <p>Rapid increase in K<sup>+</sup> is common with AKI.</p> <p>Chloride, phosphorus, and magnesium—usually elevated.</p> <p>Calcium—commonly decreased in AKI and may require replacement.</p> <p>Higher-than-normal levels can indicate dehydration or renal tubular necrosis. Lower-than-normal levels are associated with fluid volume overload or syndrome of inappropriate antidiuretic hormone secretion (SIADH).</p>

## URINE TESTS

- Volume:** In AKI, volume is variable.

Often less than 400 mL/24 hr (oliguric phase), which occurs within 24 to 48 hours after renal insult. May be less than 100 mL/24 hr (anuric phase) or more than 400 mL/24 hr (nonoliguric) when renal damage is associated with nephrotoxic agents such as contrast media or antibiotics. *Note:* Recently, practitioners have been emphasizing the importance of the volume of urine output as a marker for AKI because it's easy to measure and directly reflects glomerular filtration rate (GFR)/kidney function in real time (Dirkes, 2015).

Presence of RBCs is always pathologic (Workeneh et al, 2017). Reddish-brown, cola-, or tea-colored urine is suggestive of glomerular damage and acute tubular necrosis (ATN) or presence of myoglobin in the urine.

Increased in poor renal perfusion. Decreased in kidney disease, such as glomerulonephritis and pyelonephritis with loss of ability to concentrate. Specific gravity that is fixed at 1.010 reflects severe renal damage.

Alkaline urine (pH greater than 7) can be found in urinary tract infections (UTIs) and renal tubular necrosis.

Urine with higher osmolarity is concentrated with less water and a higher solute load, indicating a prerenal cause. Urine with decreased osmolarity is dilute with few solutes, indicating that the cause of renal failure resides in the kidney itself.

Best indicator of overall kidney function, as reduced Cr clearance correlates with increased circulating creatinine.

Usually increased if ATN is cause of AKI and if kidney is not able to reabsorb sodium, although it is typically decreased in other causes of prerenal azotemia.

(continues on page 600)

- Color:** Determine presence of RBCs, Hgb, myoglobin, and porphyrins.

- Specific gravity:** Measures density of urine compared to water with normal range of 1.005 to 1.030.

- pH:** Measures level of acidity.

- Osmolality or osmolarity:** Measures the ratio of water and solutes, such as electrolytes, acids, and other metabolic wastes, processed by the kidneys and released in urine. When body fluid is balanced, normal urine osmolarity is in the range of 300 to 900 mOsm/L.

- Cr clearance:** Calculates glomerular filtration rate (GFR) by measuring the amount of Cr cleared from the blood and filtered into urine in 24 hours.

- Sodium:** Determines hydration status and ability to conserve or excrete Na.

## DIAGNOSTIC STUDIES (contd.)

WHY IT IS DONE (continued)	WHAT IT TELLS ME (continued)
<ul style="list-style-type: none"><li><b>Fractional excretion sodium (FeNa):</b> Calculated measure of renal tubule function.</li></ul>	Reveals inability of tubules to reabsorb sodium. Readings of less than 1% indicate prerenal disorders; higher than 1% reflects intrarenal disorders.
<ul style="list-style-type: none"><li><b>Protein:</b> The protein most likely to appear in urine is albumin. The term <i>albuminuria</i> is sometimes used when a urine test detects albumin specifically.</li></ul>	High-grade proteinuria (3 to 4+) strongly indicates glomerular damage when RBCs and casts are also present. Low-grade proteinuria (1 to 2+) and WBCs may be indicative of infection or interstitial nephritis. In ATN, proteinuria is usually minimal.
<ul style="list-style-type: none"><li><b>Casts:</b> Tubules in the kidneys secrete proteins. Under some circumstances, these proteins precipitate out to form cylindrical impressions of the tubules called casts.</li></ul>	Usually signal renal disease or infection. Cellular casts with brownish pigments and numerous renal tubular epithelial cells are diagnostic of ATN. Red casts suggest acute glomerular nephritis.
<h3>OTHER DIAGNOSTIC STUDIES</h3> <ul style="list-style-type: none"><li><b>Kidney/abdominal ultrasound:</b> Imaging technique that uses high-frequency sound waves and a computer to create images of blood vessels, tissues, and organs.</li><li><b>Kidney, ureter, bladder (KUB) x-ray:</b> X-ray of the abdomen, showing the kidneys, ureters, and bladder.</li><li><b>Computed tomography (CT) scan, with or without enhancement:</b> X-ray procedure that uses a computer to produce a detailed picture of a cross section of the body.</li><li><b>Magnetic resonance imaging (MRI):</b> Imaging test that uses powerful magnets and radio waves to create pictures of the body. It does not use radiation.</li><li><b>CT or MRI urography:</b> Examines the urinary tract before and after administration of intravenous contrast material that includes excretory phase images.</li><li><b>Intravenous pyelogram (IVP) also called intravenous urography (IVU):</b> X-ray examination and fluoroscopic visualization of the kidneys, ureters, and bladder using contrast material.</li><li><b>Aortorenal angiography:</b> Fluoroscopic examination using contrast to examine the renal blood vessels for signs of blockage or abnormalities.</li><li><b>Endourology:</b> Diagnostic and therapeutic operative procedures performed through instruments—cystoscopic, pelviscopic, or laparoscopic.</li><li><b>Renal biopsy</b></li></ul>	Evaluates existing renal disease and obstruction of the urinary collecting system. The degree of hydronephrosis does not necessarily correlate with the degree of obstruction. Demonstrates size and structure of kidneys, ureters, and bladder; reveals presence of abnormalities, such as cysts, tumors, or stones. Ultrasound and computed tomography (CT) are modalities of first choice in renal imaging.  Can be used in case of compromised renal function, severe contrast allergy, or in case radiation exposure is a problem (e.g., in children and pregnant women) or as a problem-solving modality when CT findings are nondiagnostic. These tests provide detailed anatomic depiction of each of the major portions of the urinary tract—the kidneys, intrarenal collecting systems, ureters, and bladder—and thus allow for comprehensive evaluation of the entire urinary system at work. Magnetic resonance (MR) has the advantage of not using ionizing radiation and the potential to provide more functional information than CT. This test has largely been replaced by CT, CT urography, and MRI as the primary test for evaluating the urinary system (Fulgham & Bishoff, 2011). However, it may be used alone or in combination with CT to identify filling defects such as caused by trauma, stones, or tumors. Determines if blood vessel blockage is reducing renal flow.  Provides direct visualization of urethra, bladder, ureters, and kidneys to diagnose problems or to biopsy or remove small lesions or calculi. May be indicated when renal function does not return for a prolonged time.

### NURSING PRIORITIES

1. Reestablish or maintain fluid and electrolyte balance.
2. Prevent complications.
3. Provide emotional support for client and significant other (SO).
4. Provide information about disease process, prognosis, and treatment needs.

### DISCHARGE GOALS

1. Homeostasis achieved.
2. Complications prevented or minimized.
3. Current situation dealt with realistically by client/family.
4. Disease process, prognosis, and therapeutic regimen understood.
5. Plan in place to meet needs after discharge.

**NURSING DIAGNOSIS:** **excess Fluid Volume****May Be Related To**

Compromised regulatory mechanism (renal failure)  
Excessive sodium intake; excessive fluid intake

**Possibly Evidenced By**

Intake exceeds output, oliguria; alteration in specific gravity  
Alteration in blood pressure (BP), increase in central venous pressure (CVP); jugular vein distention  
Edema, weight gain over short period of time  
Pulmonary congestion  
Alteration in mental status, restlessness  
Decrease in Hgb/Hct, electrolyte imbalance, azotemia

**Desired Outcomes/Evaluation Criteria—Client Will****Fluid Overload Severity NOC**

Demonstrate stabilized fluid volume as evidenced by balanced intake and output with urinary specific gravity and other laboratory studies near normal, stable weight and vital signs within client's normal range, and absence of edema.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Hypervolemia Management NIC</b>	
<b>Independent</b>	
Record accurate intake and output (I&O). Include "hidden" fluids, such as intravenous (IV) antibiotic additives, liquid medications, ice chips, and frozen treats. Measure GI losses and estimate insensible losses, such as diaphoresis.	Low urine output less than 400 mL/24 hr may be first indicator of acute failure, especially in a high-risk client. Accurate I&O are necessary for determining fluid replacement needs and reducing risk of fluid overload. Note: Hypervolemia occurs in the anuric phase of AKI.
Monitor urine specific gravity.	Measures the kidney's ability to concentrate urine. In intrarenal failure, specific gravity is usually equal to or less than 1.010, indicating loss of ability to concentrate the urine.
Weigh daily at same time of day, on same scale, with same equipment and clothing.	Daily body weight is best monitor of fluid status. A weight gain of more than 0.5 kg/d suggests fluid retention.
Assess skin, face, and dependent areas for edema. Evaluate degree of edema (on scale of +1 to +4).	Edema occurs primarily in dependent tissues of the body, such as hands, feet, and lumbosacral area. Client can gain up to 10 lb (4.5 kg) of fluid before pitting edema is detected. Periorbital edema may be a presenting sign of this fluid shift because these fragile tissues are easily distended by even minimal fluid accumulation.
Monitor heart rate, BP, and central venous pressure (CVP), if available.	Tachycardia and hypertension can occur because of (1) failure of the kidneys to excrete urine, (2) excessive fluid resuscitation during efforts to treat hypovolemia or hypotension, and (3) changes in the renin-angiotensin system, which helps regulate long-term blood pressure and blood volume. Note: Invasive monitoring may be needed for assessing intravascular volume, especially in clients with poor cardiac function.
Auscultate lung and heart sounds.	Fluid overload may lead to pulmonary edema and heart failure (HF), as evidenced by development of adventitious breath sounds and extra heart sounds. (Refer to ND: risk for decreased Cardiac Output, below.)
Assess level of consciousness; investigate changes in mentation and presence of restlessness.	May reflect fluid shifts, accumulation of toxins, acidosis, electrolyte imbalances, or developing hypoxia.
Plan oral fluid replacement with client, within multiple restrictions. Intersperse desired beverages throughout 24 hours. Vary offerings, such as hot, cold, and frozen.	Helps avoid periods without fluids, minimizes boredom of limited choices, and reduces sense of deprivation and thirst.

(continues on page 602)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<b>Collaborative</b> Correct any reversible cause of AKI, such as replacing blood losses, discontinuing nephrotoxic drug, removing obstruction via surgery.	Current treatment for AKI is mainly supportive. Maintenance of circulating volume and correction of biochemical abnormalities are the primary goals of treatment. Kidneys may be able to return to near-normal functioning, thus preventing or limiting long-term residual effects.
Insert and maintain indwelling catheter, as indicated.	Catheterization excludes lower tract obstruction and provides means of accurate monitoring of urine output during acute phase; however, indwelling catheterization may be contraindicated because of increased risk of infection.
Monitor laboratory and diagnostic studies, such as the following:	
BUN, Cr	Assesses progression and management of renal dysfunction, failure. Note: Dialysis is indicated if ratio is higher than 10:1 or if therapy fails to correct fluid overload or metabolic acidosis.
Serum sodium	Hyponatremia may result from fluid overload (dilutional) or kidney's inability to conserve sodium. Hypernatremia indicates total body water deficit.
Serum potassium	Lack of renal excretion or selective retention of potassium by the tubules leads to hyperkalemia, requiring prompt intervention.
Hgb/Hct	Decreased values may indicate hemodilution associated with hypervolemia; however, during prolonged failure, anemia frequently develops as a result of decreased RBC production. Other possible causes—active or occult hemorrhage—should also be evaluated.
Serial chest x-rays	Increased cardiac size, prominent pulmonary vascular markings, pleural effusion, and infiltrates indicate acute responses to fluid overload or chronic changes associated with renal failure and HF.
Administer and restrict fluids, as indicated.	Fluid management is usually calculated to replace output from all sources as well as estimate insensible losses due to metabolism and diaphoresis. Prerenal failure is treated with volume replacement and vasopressors. The oliguric client with adequate circulating volume or fluid overload who is unresponsive to fluid restriction and diuretics requires dialysis.
Administer medication, as indicated, for example:	
Diuretics, such as furosemide (Lasix), bumetanide (Bumex), torsemide (Demadex), and mannitol (Osmitrol)	Given early in oliguric phase of AKI in an effort to convert to diuretic phase, flush the tubular lumen of debris, reduce hyperkalemia, and promote adequate urine volume.
Vasodilators, such as fenoldopam (Corlopam)	May be given to decrease systemic vascular resistance (SVR) and increase renal blood flow. It has been noted to improve renal function in patients with severe hypertension.
Antihypertensives, such as clonidine (Catapres), methyldopa (Aldomet), and prazosin (Minipress)	May be given to treat hypertension by counteracting effects of decreased renal blood flow and/or circulating volume overload.
Prepare for renal replacement therapy (RRT) as indicated, such as hemodialysis (HD), peritoneal dialysis (PD), or continuous renal replacement therapy (CRRT).	Done to reduce volume overload, correct electrolyte and acid-base imbalances, and remove toxins. The type of dialysis chosen for AKI depends on the degree of hemodynamic compromise and client's ability to withstand the procedure. Note: Although it technically can be used, peritoneal dialysis is not frequently used in patients with AKI (Workeneh et al, 2017). (Refer to CP: Renal Dialysis.)

**NURSING DIAGNOSIS:** risk for decreased Cardiac Output**Possibly Evidenced By**

Altered preload—fluid deficit, hypovolemia caused by vasodilation, insufficient intake, excessive fluid losses

Altered afterload—fluid overload, fluid shifts (venous distention)

Alteration in heart rate or rhythm (e.g., potassium, calcium imbalance; uremic effects on cardiac muscle)

**Desired Outcomes/Evaluation Criteria—Client Will****Cardiac Pump Effectiveness NOC**

Maintain cardiac output as evidenced by BP and HR and rhythm within client's usual limits and peripheral pulses strong and equal, with appropriate capillary refill time.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Hemodynamic Regulation NIC</b>	
<i>Independent</i>	
Monitor BP and heart rate.	Fluid volume excess, combined with hypertension, which often occurs in renal failure, and effects of uremia increase cardiac workload and can lead to cardiac failure. In AKI, cardiac failure is usually reversible.
Observe electrocardiogram (ECG) or telemetry for changes in rhythm.	Changes in electromechanical function may become evident in response to accumulation of toxins and electrolyte imbalance. For example, hyperkalemia is associated with a peaked T wave, wide QRS complex, prolonged PR interval, and flattened or absent P wave. Hypokalemia is associated with flattened T wave, peaked P wave, and appearance of U waves. Prolonged QT interval may reflect calcium deficit.
Auscultate heart sounds.	Development of $S_3/S_4$ is associated with fluid volume excess and congestive HF. Pericardial friction rub may be only manifestation of uremic pericarditis, requiring prompt intervention and, possibly, acute dialysis.
Assess color of skin, mucous membranes, and nailbeds. Note capillary refill time.	Pallor may reflect vasoconstriction or anemia—common in AKI, whether associated with actual blood loss or abnormalities in life of RBCs. Cyanosis is a late sign and is related to pulmonary congestion or cardiac failure. A long capillary refill time is associated with hypovolemic states.
Note occurrence of cardiac dysrhythmias and changes in blood pressure, especially when accompanied by mental status changes, muscle and generalized weakness.	These are clinical manifestations of magnesium deficiency (along hypocalcemia and hypokalemia) and include risk of cardiac arrest. Note: Magnesium deficiency in AKI has been associated with nonrecovery of renal function in the intensive care unit (ICU) population (Fulop et al, 2017; Tomasi et al, 2013)
Investigate reports of muscle cramps, numbness or tingling of fingers, with muscle twitching and hyperreflexia.	These are symptoms of hypocalcemia. Calcium levels are typically somewhat decreased with AKI. If phosphorus levels are also high, hypocalcemia can become severe, which can also affect cardiac contractility and function.
Maintain bedrest or encourage adequate rest and provide assistance with care and desired activities.	Reduces oxygen consumption and cardiac workload.
<i>Collaborative</i>	
Monitor laboratory studies, such as the following:	
Potassium	During oliguric phase, hyperkalemia is present but often shifts to hypokalemia in diuretic or recovery phase. Any potassium value associated with ECG changes requires intervention. Note: A serum level of 6.5 mEq or higher constitutes a medical emergency.
Calcium	In addition to its own cardiac effects, calcium deficit enhances the toxic effects of potassium.

(continues on page 604)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Phosphorus	May be abnormal because of reduced renal excretion or excess release of cellular phosphate.
Magnesium	In acute renal failure, hypermagnesemia can occur during the oliguric phase, then return to normal during the diuretic phase. If a client receives exogenous magnesium (e.g., magnesium-containing laxative or antacid) during the oliguric phase, severe hypermagnesemia can result, especially if the patient is acidotic. Dialysis or calcium administration may be necessary to combat the CNS-depressive effects of an elevated serum magnesium level.
Administer and restrict fluids as indicated. (Refer to NDs: excess Fluid Volume and risk for deficient Fluid Volume.)	Cardiac output depends on circulating volume—affected by both fluid excess and deficit—and myocardial muscle function.
Provide supplemental oxygen, as indicated.	Maximizes available oxygen for myocardial uptake to reduce cardiac workload and cellular hypoxia.
Administer medications, as indicated:	
Inotropic agents	May be used to improve cardiac output by increasing myocardial contractility and stroke volume.
Calcium gluconate	Serum calcium is often low but usually does not require specific treatment in AKI. Calcium gluconate may be given to treat hypocalcemia and to offset the effects of hyperkalemia by modifying or reducing cardiac irritability.
Aluminum hydroxide gels (Amphojel, Basalgel)	Increased phosphate levels may occur as a result of failure of glomerular filtration and require use of phosphate-binding antacids to limit phosphate absorption from the GI tract.
Glucose and insulin solution	Temporary measure to lower serum potassium by driving potassium into cells when cardiac rhythm is endangered.
Sodium bicarbonate or sodium citrate	May be used to correct metabolic acidosis or hyperkalemia by increasing serum pH if client is severely acidotic. Used with caution as it can exacerbate fluid overload and cause tetany by decreasing the ionized calcium concentration. Acidosis that does not respond to medical therapy is an indication for dialysis.
Prepare for and assist with dialysis, as necessary.	May be indicated for persistent dysrhythmias and progressive HF unresponsive to other therapies.

### NURSING DIAGNOSIS: risk for deficient Fluid Volume

#### Possibly Evidenced By

Active fluid loss (e.g., excessive loss of fluid losses through urine, nasogastric [NG] or wound drainage; [diuretic phase of AKI])  
Insensible losses—diaphoresis; fever

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Fluid Balance NOC

Display I&O near balance, good skin turgor, moist mucous membranes, palpable peripheral pulses, stable weight and vital signs, and electrolytes within normal range.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Fluid Monitoring NIC</b> <i>Independent</i> Measure I&O accurately. Weigh daily.	Helps estimate fluid replacement needs. Note: Rising urinary volume and delayed return of tubular reabsorption capabilities may lead to hypovolemia.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Calculate insensible fluid losses.	Fluid intake should approximate losses through urine, nasogastric (NG) or wound drainage, and insensible losses—diaphoresis and metabolism. Note: Some sources believe that fluid replacement should not exceed two-thirds of the previous day's output to prevent prolonging the diuresis.
Encourage fluid intake. Provide allowed fluids throughout 24-hour period.	Diuretic phase of AKI may revert to oliguric phase if fluid intake is not maintained or nocturnal dehydration occurs.
Monitor BP, noting postural changes, and heart rate.	Orthostatic hypotension and tachycardia suggest hypovolemia.
Note signs and symptoms of dehydration, such as dry mucous membranes, thirst, dulled sensorium, and peripheral vasoconstriction.	In diuretic or postobstructive phase of renal failure, urine output can exceed 3 L/d. Extracellular fluid (ECF) volume depletion activates the thirst center, and sodium depletion causes persistent thirst, unrelieved by drinking water. Continued fluid losses and inadequate replacement may lead to hypovolemic state.
<b>Collaborative</b>	
Monitor laboratory studies, such as sodium.	In nonoliguric AKI or in diuretic phase of AKI, large urine losses may result in sodium wasting, while elevated urinary sodium acts osmotically to increase fluid losses. Restriction of sodium may be indicated to break the cycle.

### NURSING DIAGNOSIS: risk for Infection

#### Possibly Evidenced By

Chronic illness; malnutrition  
Invasive procedures/devices; alteration in skin integrity  
Immunosuppression; decrease in hemoglobin [anemia]

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Infection Severity NIC

Experience no signs or symptoms of infection.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Infection Protection NIC</b>	
<b>Independent</b>	
Model and promote good handwashing by client and staff.	Reduces risk of cross-contamination.
Avoid invasive procedures, instrumentation, and manipulation of indwelling catheters whenever possible. Use aseptic technique when caring for IVs and invasive lines. Change site and dressings per protocol. Note edema and purulent drainage.	Limits introduction of bacteria into body. Early detection and treatment of developing infection may prevent sepsis.
Provide routine catheter care and promote meticulous perianal care. Keep urinary drainage system closed and remove indwelling catheter as soon as possible.	Reduces bacterial colonization and risk of ascending urinary tract infection (UTI).
Encourage deep breathing, coughing, and frequent position changes.	Prevents atelectasis and mobilizes secretions to reduce risk of pulmonary infections. Note: Sepsis can be present when AKI occurs but also can follow AKI in a critically ill client.
Assess skin integrity. Note if client is scratching, reports itching. (Refer to CP: Renal Failure: Chronic; ND: risk for impaired Skin Integrity.)	Excoriations from scratching may become secondarily infected.

(continues on page 606)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Monitor vital signs.	Fever higher than 100.4°F (38.0°C) with increased pulse and respirations is typical of increased metabolic rate resulting from inflammatory process, although sepsis can occur without a febrile response.
<b>Collaborative</b> Monitor laboratory studies, such as WBC count with differential.	Although elevated WBCs may indicate generalized infection, leukocytosis is commonly seen in AKI and may reflect inflammation or injury within the kidney. A shifting of the differential to the left is indicative of infection.
Obtain specimen(s) for culture and sensitivity and administer appropriate antibiotics, as indicated.	Verification of infection and identification of specific organism aids in choice of the most effective treatment. Note: A number of anti-infective agents require adjustments of dose or time while renal clearance is impaired.

### NURSING DIAGNOSIS: **deficient Knowledge regarding condition, prognosis, treatment, self-care, and discharge needs**

#### May Be Related To

Insufficient information or interest in learning; insufficient knowledge of resources  
Alteration in cognitive functioning or memory

#### Possibly Evidenced By

Insufficient knowledge  
Inaccurate follow-through of instructions; development of preventable complications

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Knowledge: Kidney Disease Management NOC

Verbalize understanding of condition, disease process, prognosis, and potential complications.  
Verbalize understanding of therapeutic needs.  
Participate in learning process.  
Initiate necessary lifestyle changes and participate in treatment regimen.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Teaching: Disease Process NIC</b>	
<b>Independent</b>	
Review disease process, prognosis, and precipitating factors, if known.	Provides knowledge base from which client can make informed choices.
Explain level of renal function after acute episode is over.	Client may experience residual defects in kidney function, which may or may not be permanent.
Discuss renal dialysis or transplantation if these are likely options for the future.	Although these options would have been previously presented by the physician, client may now be at a point when options need to be considered and decisions made and may desire additional input.
Review dietary plan and restrictions. Include fact sheet listing food and fluid restrictions.	Adequate nutrition is necessary to promote healing and tissue regeneration; adherence to restrictions may prevent complications.
Encourage client to observe characteristics of urine and amount and frequency of output.	Changes may reflect alterations in renal function and need for dialysis.
Establish regular schedule for weighing.	Useful tool for monitoring fluid and dietary status and needs.
Review fluid intake and restriction (if indicated). Remind client to spread fluids over entire day and to include all fluids (e.g., ice) in daily fluid counts.	Depending on the cause and phase of AKI, client may need to either restrict or increase intake of fluids.
Discuss activity restriction and gradual resumption of desired activity. Encourage use of energy-saving and relaxation techniques and diversional activities.	Client with severe AKI may need to restrict activity and may feel weak for an extended period during lengthy recovery phase, requiring measures to conserve energy and reduce boredom and depression.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Discuss reality of continued presence of fatigue.	Decreased metabolic energy production, presence of anemia, and states of discomfort commonly result in fatigue.
Determine and prioritize activities of daily living (ADLs) and personal responsibilities. Identify available resources and support systems.	Helps client manage lifestyle changes that may be needed to meet personal and family needs.
Recommend scheduling activities with adequate rest periods.	Prevents excessive fatigue and conserves energy for healing and tissue regeneration.
Review medication use. Encourage client to discuss all medications, including over-the-counter (OTC) drugs and herbal supplements, with healthcare provider.	Medications that are concentrated in or excreted by the kidneys can cause toxic cumulative reactions and permanent damage to kidneys. Some supplements may interact with prescribed medications and may contain electrolytes.
Emphasize necessity of follow-up care and laboratory studies.	Renal function can be slow to return—up to 12 months following AKI—and deficits may persist, requiring frequent monitoring to avoid complications.
Identify symptoms requiring medical intervention, such as decreased urinary output, sudden weight gain, presence of edema, lethargy, bleeding, signs of infection, and altered mental status.	Prompt evaluation and intervention may prevent serious complications and progression to chronic renal failure (CRF).

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

- **risk for imbalanced Fluid Volume (specify)**—dependent on cause, duration, and stage of recovery
- **Fatigue**—disease state, malnutrition, anemia
- **risk for Infection**—immunosuppression, malnutrition, increased environmental exposure
- **ineffective Health Management**—complexity of therapeutic regimen, economic difficulties, perceived benefit/barriers

## RENAL FAILURE: CHRONIC KIDNEY DISEASE AND END-STAGE RENAL DISEASE

### I. Pathophysiology

- a. Renal failure is the end result of chronic kidney disease (CKD), which is the consequence of gradual, progressive destruction of nephrons and decrease in glomerular filtration rate (GFR) over time, resulting in loss of kidney function that produces major changes in all body systems.
  - b. CKD is defined as an abnormality in kidney function or structure for more than 3 months and is classified based on cause, glomerular filtration rate (GFR) category, and albuminuria category (Kidney Disease Improving Global Outcomes [KDIGO], 2012; The Renal Association, 2017; Smith, 2016). The risk of CKD progressing to kidney failure increases as kidney function diminishes and/or urine protein (albuminuria) increases.
  - c. Client with CKD generally experiences progressive loss of kidney function and is at risk for end-stage renal disease (ESRD). The rate of progression is unique to the individual and depends on age, the underlying diagnosis, the success of preventive measures.
- II. CKD Stages (KDIGO, 2012; Pradeep, 2017)** Chronic kidney disease is classified in stages G1 to G5 (based on the GFR

and A1 to A3 (based on the albumin to creatinine ratio [ACR]). These classifications correspond to the degree of nephron loss and changes in GFR and are used in conjunction with other markers of kidney disease such as albuminuria, hematuria, and electrolyte abnormalities due to tubular disorders, renal histological abnormalities, and/or structural abnormalities detected by imaging. (Note: People with CKD stages 1 to 3 are frequently asymptomatic, and despite reduction in GFR, they do not experience clinically evident disturbances in water or electrolyte balance or endocrine/metabolic derangements.)

- a. Stage 1
  - i. GFR may be normal or slightly higher than normal ( $>90 \text{ mL/min}/1.73 \text{ m}^2$ ).
  - ii. Albuminuria (excretion  $>30 \text{ mg}/24 \text{ hr}$  or albumin/creatinine ratio  $>30 \text{ mg/g}$  [ $>3 \text{ mg/mmol}$ ])
  - iii. Urine sediment abnormalities, electrolyte and other abnormalities (tubular disorders), and histological and structural abnormalities may be identified in lab or imaging studies.
  - iv. Kidney dysfunction is present; however, it may be undiagnosed due to lack of symptoms.

(continues on page 608)

- b. Stage 2
    - i. GFR is mildly decreased (60 to 89 mL/min/1.73 m<sup>2</sup>), slight elevation in BUN/Cr
    - ii. Albuminuria (excretion >30 mg/24 hr or albumin/creatinine ratio >30 mg/g [>3 mg/mmol])
    - iii. Urine sediment abnormalities, electrolyte and other abnormalities (tubular disorders), and histological and structural abnormalities
    - iv. Client may be asymptomatic or have hypertension.
    - v. Polyuria and nocturia may be present—high-output failure.
  - c. Stages 3a and 3b
    - i. Moderate reduction in GFR (45 to 59 mL/min/1.73 m<sup>2</sup>) **in 3a** and (30 to 44 mL/min/1.73 m<sup>2</sup>) **in 3b**
    - ii. Albuminuria (excretion >30 mg/24 hr or albumin/creatinine ratio >30 mg/g [>3 mg/mmol])
    - iii. Fluid and electrolyte abnormalities may be present but are not clinically significant.
    - iv. Client may be asymptomatic or have hypertension.
  - d. Stage 4
    - i. Severe reduction in GFR (15 to 29 mL/min/1.73 m<sup>2</sup>) and/or very high albuminuria (>300 mg/24 hr)
    - ii. Client has endocrine/metabolic derangements or disturbances in water or electrolyte balance, protein-energy malnutrition, loss of lean body mass, muscle weakness; peripheral and pulmonary edema
    - iii. Timely referral to a nephrologist when glomerular filtration rate approaches 30 mL/min/1.73 m<sup>2</sup> is believed to improve ESRD outcome and appropriate selection of dialysis modality.
  - e. Stage 5
    - i. End-stage renal disease/kidney failure (GFR <15 mL/min/1.73 m<sup>2</sup>, or on dialysis)
    - ii. Client has metabolic acidosis, cardiovascular complications such as pericarditis, encephalopathy, neuropathies, and many other manifestations demonstrating end-stage disease.
- III. Etiology (Pradeep, 2017)**
- a. Multiple causes, including (but not limited to):
    - i. Primary renal (i.e., primary glomerular and tubular) disorders (e.g., polycystic kidney disease, glomerulonephritis, IgA nephropathy)
    - ii. Acute tubular necrosis (ATN) from unresolved acute kidney injury (AKI)
    - iii. Diabetes (40%) and hypertension (25.2%) are responsible for most cases of ESRD resulting in dialysis (Alper et al, 2017).
- iv. Chronic infections: glomerulonephritis, pyelonephritis, beta-hemolytic streptococci infection; hepatitis B and C; HIV; syphilis
  - v. Vascular diseases: hypertensive nephrosclerosis, renal artery stenosis, renal vein thrombosis, vasculitis
  - vi. Obstructive processes: longstanding renal calculi, benign prostatic hyperplasia (BPH)
  - vii. Cystic disorders: polycystic or medullary kidney disease
  - viii. Collagen and connective tissue diseases: rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), and collagen vascular disease
  - ix. Tumors: malignant (multiple myeloma) or benign
  - x. Genetics: Although most cases of CKD are acquired, researchers have begun to identify genetic contributions to increased risk for development or progression of CKD.
  - xi. Nephrotoxic agents: drugs, such as aminoglycosides, tetracyclines; contrast dyes; heavy metals, NSAIDs
  - b. Highest incidence of ESRD occurs in individuals older than age 70 years; men are 64% more likely than women to develop ESRD (although CKD is more common in women than men [16% vs 13%]), and African Americans are three times more likely than whites to have ESRD (Alper et al, 2017; Centers for Disease Control and Prevention [CDC], 2017; Pradeep, 2017).

#### IV. Statistics

- a. Morbidity: In 2015, 124,111 new cases of end-stage renal disease (ESRD) were reported with a total of nearly 500,000 patients receiving dialysis treatment and well over 200,000 living with a kidney transplant (United States Renal Data System [USRDS], 2017).
- b. Mortality: In 2013, adjusted mortality rates remained higher for Medicare patients with CKD (117.9/1000) than for those without CKD (47.5/1000), and these rates increased with CKD severity, although this gap narrowed during the period from 2001 to 2013 (National Institute of Diabetes and Digestive and Kidney Diseases [NIDDK], 2016a). Deaths in the dialysis population are associated with (1) cardiovascular disease, (2) sepsis, and (3) cerebrovascular disease (Pradeep, 2017). Mortality rates continue to decrease for dialysis and transplant patients, having fallen by 28% and 40%, respectively, since 1996 (NIDDK, 2016a).
- c. Cost: In 2015, the total Medicare spending for beneficiaries with kidney disease was nearly \$100 billion. This included over \$64 billion in spending for all Medicare beneficiaries who have CKD and another \$34 billion for beneficiaries with ESRD (USRDS, 2017).

#### G L O S S A R Y

**ACR (albumin to creatinine ratio):** Determines the relationship between the albumin and creatinine in the urine and estimates the amount of albumin excreted in 24 hours. A urine albumin-to-creatinine ratio above 30 mg/g is higher than normal.

**Acute tubular necrosis (ATN):** Structural injury or tissue necrosis within the kidney, caused by ischemia or toxic injury. Necrosis is usually patchy, but injury can be widespread.

**Albuminuria:** Too much albumin in the urine is a sign of **kidney disease**. Albumin is a protein found in the blood

and should not be found in urine. A damaged kidney lets some albumin pass into the urine.

**Anuria:** Urine output less than 100 mL/24 hr.

**Azotemia:** Buildup of nitrogenous waste products, specifically urea, in the blood (BUN).

**Chronic kidney disease or chronic renal failure:**

Kidney damage or decreased kidney GFR of less than 60 mL/min/1.73 m<sup>2</sup> for 3 or more months.

**Ecchymosis:** Superficial bleeding under the skin—purple or black-and-blue bruise.

**G L O S S A R Y** (continued)

**End-stage renal disease (ESRD):** GFR less than 15 mL/min or receiving dialysis.

**Glomerular filtration rate (GFR):** Rate of fluid filtration through the kidney glomeruli.

**Nephrotoxins:** Chemical substances, including medications that can cause kidney damage.

**Nocturia:** Frequent urination after retiring to bed.

**Oliguria:** Urinary output less than 400 mL/24 hr.

**Osteitis fibrosa:** Bones become soft and deformed due to increased metabolism or high bone turnover associated with increased levels of parathyroid hormone. Leads to bone pain, tenderness, and increased risk of fractures.

**Polyuria:** Excretion of large amounts (2–6 L/24 hr) of urine, lacking concentration and regulation of waste products. Occurs during diuretic phase of AKI.

**Porphyrins:** Nitrogen-containing chemical components of hemoglobin.

**Purpura:** Hemorrhagic state characterized by patches of purplish discoloration, resulting from extravasation of blood into the skin. Purpura does not blanch with pressure.

**Pyelonephritis:** Infection of the kidney medulla or cortex.

**Renal osteodystrophy:** Bone disease that occurs when the kidneys fail to maintain the proper levels of calcium and phosphorus in the blood.

**Uremia:** Toxic clinical syndrome associated with fluid, electrolyte, and hormone imbalances and metabolic abnormalities due to deterioration of renal function and the deleterious effects of azotemia on organ systems.

**CARE SETTING**

Primary care of the individual with chronic kidney disease is at the community level, although inpatient acute hospitalization may be required for life-threatening complications.

**RELATED CONCERNs**

Anemias—iron deficiency, anemia of chronic disease, pernicious, aplastic, hemolytic, page 541  
 Fluid and electrolyte imbalances (see *DavisPlus*)  
 Heart failure: chronic, page 38  
 Hypertension: severe, page 26

 Acute kidney injury (acute renal failure), page 595  
 Renal dialysis—general considerations, page 623

**CLIENT ASSESSMENT DATABASE**

Clients with chronic renal failure may not have any symptoms at all until normal kidney function declines to 20% or less. At that stage, an array of symptoms, such as the following, may appear.

DIAGNOSTIC DIVISION MAY REPORT	MAY EXHIBIT
<b>ACTIVITY/REST</b> <ul style="list-style-type: none"> <li>• Extreme fatigue, weakness, malaise</li> <li>• Sleep disturbances—insomnia, restlessness, somnolence</li> </ul>	<ul style="list-style-type: none"> <li>• Muscle weakness, loss of tone, decreased range of motion (ROM)</li> </ul>
<b>CIRCULATION</b> <ul style="list-style-type: none"> <li>• History of prolonged or severe hypertension</li> <li>• Palpitations, chest pain (angina)</li> </ul>	<ul style="list-style-type: none"> <li>• Hypertension, jugular vein distention (JVD)</li> <li>• Cardiac dysrhythmias, distant heart sounds</li> <li>• Pericardial friction rub if uremic pericarditis is present</li> <li>• Full or bounding pulses</li> <li>• Generalized tissue and pitting edema of feet, legs, and hands</li> <li>• Enlargement of liver, spleen, and heart</li> <li>• Pallor, bronze-gray, yellow skin</li> </ul>

(continues on page 610)

**CLIENT ASSESSMENT DATABASE (contd.)****MAY REPORT (continued)****MAY EXHIBIT (continued)****EGO INTEGRITY**

- Stress factors—financial, relationship
- Feelings of helplessness, hopelessness, powerlessness

**ELIMINATION**

- Decreased urinary frequency, oliguria, anuria (advanced failure)
- Abdominal bloating, diarrhea, or constipation

**FOOD/FLUID**

- Anorexia
- Heartburn, nausea, vomiting, unpleasant metallic taste in mouth
- Rapid weight gain (edema), weight loss (malnutrition)
- Use of diuretics

**HYGIENE**

- Difficulty performing activities of daily living (ADLs)

**NEUROSENSORY**

- Headache, blurred vision
- Numbness, tingling, and weakness, especially of lower extremities (peripheral neuropathy)
- Muscle cramps or twitching, “restless leg” syndrome, burning numbness of soles of feet

**PAIN/DISCOMFORT**

- Flank pain, headache, muscle cramps, or leg pain—worse at night

**RESPIRATION**

- Shortness of breath, sudden nighttime dyspnea
- Cough with or without thick, tenacious sputum

**SAFETY**

- Itching skin, frequent scratching
- Recent or recurrent infections
- Bleeding tendencies

**SEXUALITY**

- Decreased libido, amenorrhea, infertility
- Erectile dysfunction

**SOCIAL INTERACTION**

- Difficulties imposed by condition, such as unable to work, maintain social contacts, or usual role function in family

**TEACHING/LEARNING**

- Family history of polycystic disease, hereditary nephritis, urinary calculus, malignancy

- Denial, anxiety, fear, anger, irritability, personality changes

- Change in urine color—deep yellow, red, brown, cloudy
- Oliguria, may become anuric

- Muscle wasting, decreased subcutaneous fat, debilitated appearance
- Gum ulcerations; bleeding of gums, tongue
- Abdominal distention, ascites, liver enlargement (end stage)
- Changes in skin turgor and moisture
- Edema—generalized, dependent

- Thin, dry, brittle nails and hair

- Altered mental state—continuum of symptoms can be present, depending on stage of disease, such as decreased attention span, inability to concentrate, loss of memory, confusion, decreasing level of consciousness, stupor, coma
- Twitching, muscle fasciculation, seizure activity
- Gait abnormalities

- Guarding, distraction behaviors, restlessness

- Tachypnea, dyspnea, increased rate and depth (Kussmaul's respiration may be associated with metabolic acidosis)
- Cough productive of pink-tinged sputum (pulmonary edema)

- Scratch marks, petechiae, ecchymotic areas on skin
- Fever (sepsis, dehydration); normothermia may actually represent an elevation in client who has developed a lower-than-normal body temperature (effect of chronic renal failure [CRF] and depressed immune response)
- Bone fractures; calcium phosphate deposits (metastatic calcifications) in skin, soft tissues, joints; limited joint movement

**MAY REPORT (continued)****MAY EXHIBIT (continued)**

- History of poorly controlled hypertension or diabetes (high risk for renal failure), exposure to toxins, such as nephrotoxic drugs, drug overdose, environmental poisons
- Current or recent use of nephrotoxic antibiotics, angiotensin-converting enzyme (ACE) inhibitors, chemotherapy agents, heavy metals, NSAIDs, radiocontrast agents

**DISCHARGE PLAN CONSIDERATIONS**

- May require alteration or assistance with medications, treatments, supplies; transportation; homemaker or maintenance tasks

► Refer to section at end of plan for postdischarge considerations.

**DIAGNOSTIC STUDIES**

TEST	WHY IT IS DONE	WHAT IT TELLS ME
<b>BLOOD TESTS</b>		
• <b>Blood urea nitrogen (BUN):</b>	Measures the by-product of protein metabolism in the liver, filtered by the kidneys and excreted in urine.	Levels are elevated in chronic kidney disease. ESRD is characterized by marked elevation of BUN.
• <b>Creatinine (Cr):</b>	End product of muscle and protein metabolism filtered by the kidneys and excreted in urine.	The level of creatinine in the blood helps estimate the glomerular filtration rate (GFR). Can be quite elevated before symptoms of CRF are present in unmonitored client. Markedly elevated in late stage.
• <b>BUN/Cr ratio:</b>	Ratio helps determine whether factors other than kidney failure are causing changes in numbers. Normal ratio is 10:1.	Ratio is less than 10:1, especially in later stages of CRF. Impaired filtration causes reduced BUN reabsorption, thereby lowering BUN/Cr ratio.
• <b>Glomerular filtration rate (GFR):</b>	Calculated from serum Cr levels and adjusted for mean normal body surface area. GFR is approximately 90 mL/min in the healthy adult.	GFR is used to stage renal failure. Symptoms are typically absent until GFR falls below 60 (stage 3). The client in severe CRF with a GFR between 15 and 29 (stages 4–5) is a candidate for dialysis or transplantation.
• <b>Complete blood count (CBC):</b>	Battery of screening tests, which typically includes hemoglobin (Hgb); hematocrit (Hct); red blood cell (RBC) count, morphology, indices, and distribution width index; platelet count and size; and white blood cell (WBC) count and differential.	Hgb decreases because of anemia, usually less than 7 to 8 g/dL. Anemia develops from decreased renal synthesis of erythropoietin, the hormone responsible for bone marrow stimulation for RBC production. RBC survival is decreased, and bleeding tendency is increased from the uremia-induced platelet dysfunction.
• <b>Arterial blood gases (ABGs):</b>	Determines the pH and the percentage of oxygen, carbon dioxide, and bicarbonate in arterial blood.	Decreased pH. Metabolic acidosis (less than 7.2) occurs because of loss of renal ability to excrete hydrogen and ammonia or end products of protein catabolism. Bicarbonate and PCO <sub>2</sub> decreased.
• <b>Electrolytes (renalytes):</b>	Electrically charged minerals found in body tissues and blood in the form of dissolved salts that help move nutrients into and wastes out of the body's cells, maintain water balance, and stabilize the body's pH level.	
• <b>Sodium:</b>	Helps to evaluate hydration status and progression of renal failure.	May be low if kidney "wastes sodium" or normal, reflecting dilutional state of hypernatremia.

(continues on page 612)

## DIAGNOSTIC STUDIES (contd.)

WHY IT IS DONE (continued)	WHAT IT TELLS ME (continued)
<ul style="list-style-type: none"> <li>• <b>Potassium:</b> Fluctuation in levels can create life-threatening situations, affecting therapeutic choices.</li> </ul>	Elevated related to potassium retention, with decline in GFR below 20 to 25 mL/min diminishes kidney ability to excrete potassium, or with cellular shifts (acidosis), or tissue release (RBC hemolysis). In ESRD, electrocardiogram (ECG) changes may not occur until potassium is 6.5 mEq or higher. The resulting hyperkalemia poses a life-threatening emergency, which requires frequent and immediate intervention. Note: Potassium may also be decreased if client is on potassium-wasting diuretics or when client is receiving dialysis treatment.
<ul style="list-style-type: none"> <li>• <b>Phosphorus:</b> Has a direct impact on parathyroid function and bone health.</li> </ul>	As GFR declines, less phosphate is filtered and excreted; however, serum levels may remain normal initially because of increased parathyroid hormone (PTH) secretion and the associated increase in renal excretion of phosphorus. As CRF advances to stages IV and V, serum levels rise and bone complications such as osteitis fibrosa may develop.
<ul style="list-style-type: none"> <li>• <b>Calcium:</b> Important in feedback mechanism for inhibiting PTH synthesis and skeletal bone turnover.</li> </ul>	Hypocalcemia may become severe as a result of low plasma calcitriol levels impairing intestinal absorption or from calcium binding to elevated serum phosphate levels.
<ul style="list-style-type: none"> <li>• <b>Magnesium:</b> Helps maintain normal muscle and nerve function, keeps heart rhythm steady, promotes normal blood pressure, and is known to be involved in energy metabolism and protein synthesis.</li> </ul>	In end-stage renal disease, the limited ability of the kidney to excrete an increased magnesium load may result in toxic concentrations in serum. While hypermagnesemia is a hazard when magnesium-containing drugs are given, magnesium balance may be normal or even decreased in many uremic individuals. This is usually due to decreased dietary intake combined with the impaired intestinal magnesium absorption that characterizes late-stage renal failure.
<ul style="list-style-type: none"> <li>• <b>Proteins (especially albumin):</b> Evaluates nutritional status and predicts mortality in clients receiving dialysis.</li> </ul>	Decreased serum level may reflect protein loss via urine, fluid shifts, decreased intake, or decreased synthesis because of malnutrition.
<ul style="list-style-type: none"> <li>• <b>Serum osmolality:</b> Measures the amount of chemicals dissolved in the serum. Kidneys excrete or reabsorb water to keep osmolality in range of 285 to 295 mOsm/kg. Chemicals that affect serum osmolality include sodium, chloride, bicarbonate, proteins, and glucose.</li> </ul>	Higher than 285 mOsm/kg; often equal to urine.
<b>URINE TESTS</b>	
<ul style="list-style-type: none"> <li>• <b>Volume:</b> Reflection of declining renal function, possible development of AKI superimposed on CRF.</li> </ul>	Usually less than 400 mL/24 hr (oliguria) or urine is absent (anuria).
<ul style="list-style-type: none"> <li>• <b>Color:</b> Changes in color or clarity indicate developing complications.</li> </ul>	Abnormally cloudy urine may be caused by pus, bacteria, fat, colloidal particles, phosphates, or urates. Dirty, brown sediment indicates presence of RBCs, Hgb, myoglobin, and porphyrins.
<ul style="list-style-type: none"> <li>• <b>Specific gravity:</b> Measures density of urine compared to water, with normal range of 1.005 to 1.030.</li> </ul>	Less than 1.015 or fixed at 1.010 reflects severe renal damage.
<ul style="list-style-type: none"> <li>• <b>Protein (albuminuria):</b> Dipstick test used as a screening tool to detect glomerular injury (prevalent in persons with diabetes, hypertension, or glomerular disease) that has caused glomeruli to lose selective permeability and leak protein, particularly albumin, which is excreted in the urine.</li> </ul>	High-grade persistent proteinuria (3 to 4+) strongly indicates glomerular damage, especially when RBCs and casts are also present. Low-grade proteinuria (1 to 2+) and WBCs may be indicative of infection or interstitial nephritis.
<ul style="list-style-type: none"> <li>• <b>Total protein-Cr (albumin-Cr) ratio:</b> Spot urine collection for total protein-to-creatinine ratio allows reliable approximation (extrapolation) of total 24-hour urinary protein excretion.</li> </ul>	A value greater than 3.0 to 3.5 g is within the nephrotic range; less than 2.0 g is characteristic of tubulointerstitial problems.
<ul style="list-style-type: none"> <li>• <b>Osmolality:</b> Measures the ratio of water and solutes, such as electrolytes, acids, and other metabolic wastes, processed by the kidneys and released in urine. When body fluid is balanced, normal urine osmolality is in the range of 300 to 900 mOsm/kg.</li> </ul>	Less than 350 mOsm/kg is indicative of tubular damage, and urine/serum ratio is often 1:1.

WHY IT IS DONE (continued)	WHAT IT TELLS ME (continued)
<ul style="list-style-type: none"> <li>• <b>Cr clearance:</b> Calculates GFR by measuring the amount of Cr cleared from the blood and filtered into urine in 24 hours.</li> <li>• <b>Sodium:</b> Determines hydration status and ability to conserve or excrete Na.</li> </ul>	<p>Best indicator of overall kidney function, as reduced Cr clearance correlates with increased circulating Cr. May be significantly decreased—less than 80 mL/min in early kidney disease; less than 10 mL/min in ESRD.</p> <p>More than 40 mEq/L because kidney is not able to reabsorb sodium.</p>
<b>OTHER DIAGNOSTIC STUDIES</b>	
<ul style="list-style-type: none"> <li>• <b>Renal ultrasound:</b> Imaging technique that uses high-frequency sound waves and a computer to create images of blood vessels, tissues, and organs.</li> </ul>	Kidney size can be correlated with certain conditions—large kidney may be present in hyperfiltration, or small, echogenic kidney may be associated with advanced kidney disease.
<ul style="list-style-type: none"> <li>• <b>Doppler ultrasound/duplex Doppler study:</b> Test that uses high-frequency sound waves (ultrasound) to measure the amount of blood flow through your arteries and veins.</li> </ul>	Ultrasound can also document presence of tumors, polycystic disease, or other obstruction in upper urinary system.
<ul style="list-style-type: none"> <li>• <b>Computed tomographic (CT) scans:</b> X-ray procedure that uses a computer to produce a detailed picture of a cross section of the body.</li> </ul>	Noninvasive study to evaluate problems in the kidneys caused by restricted blood flow (renal artery stenosis).
<ul style="list-style-type: none"> <li>• <b>Magnetic resonance imaging (MRI):</b> Imaging technique that uses a magnetic field and radio waves to create detailed images of the organs and tissues within the body.</li> </ul>	Demonstrates vessel disorders and kidney mass.
<ul style="list-style-type: none"> <li>• <b>Kidney, ureter, bladder (KUB) x-ray:</b> X-ray of the abdomen, showing the kidneys, ureters, and bladder.</li> </ul>	Useful in person who requires a CT scan but who cannot receive intravenous contrast; reliable in the diagnosis of renal vein thrombosis.
<ul style="list-style-type: none"> <li>• <b>Aortorenal angiography:</b> Fluoroscopic examination, which uses contrast to examine the renal blood vessels for signs of blockage or abnormality.</li> </ul>	Demonstrates size and structure of kidneys, ureters, and bladder; reveals presence of abnormalities, such as cysts, tumors, or stones.
<ul style="list-style-type: none"> <li>• <b>Renal biopsy:</b> Percutaneous renal biopsy currently is performed most often with ultrasound guidance.</li> </ul>	Assesses renal circulation and identifies extravascularities and masses. <i>Note:</i> Contrast media can precipitate renal failure in damaged kidney.
	Biopsy is generally indicated when renal impairment or proteinuria approaching the nephrotic range is present and diagnosis is still unclear.

## NURSING PRIORITIES

1. Maintain homeostasis.
2. Prevent complications.
3. Provide information about disease process, prognosis, and treatment needs.
4. Support adjustment to lifestyle changes.

## DISCHARGE GOALS

1. Fluid and electrolyte balance stabilized.
2. Complications prevented or minimized.
3. Disease process, prognosis, and therapeutic regimen understood.
4. Dealing realistically with situation and initiating necessary lifestyle changes.
5. Plan in place to meet needs after discharge.

### NURSING DIAGNOSIS: risk for Electrolyte Imbalance

#### Possibly Evidenced By

Renal dysfunction; compromised regulatory function  
Excessive fluid volume; vomiting diarrhea  
Insufficient fluid volume

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Electrolyte & Acid/Base Balance NOC

Be free of complications resulting from electrolyte imbalances (e.g., muscle weakness/cramps, fatigue, dysrhythmias, impaired cognition)

ACTIONS/INTERVENTIONS	RATIONALE
<b>Electrolyte Management [NIC]</b>	
<b>Independent</b>	
Assess specific client risk, noting disease process that may lead to/exacerbate electrolyte imbalances (e.g., chronic kidney disease, noncompliance with kidney diet; home dialysis program; presence of other conditions, such as diabetes/other endocrine disorders, heart failure with chronic use of diuretics).	Helps to identify potential concerns requiring evaluation and intervention.
Note client's age and developmental level, which can increase the risk for electrolyte imbalance.	This risk group may include the elderly or individuals unable to meet their own needs or monitor their health status (e.g., client who is unconscious for unknown cause or length of time; homeless person, trauma victim).
Review client's daily medications. Discuss client's medications with primary healthcare provider to determine if changes should or can be made in client's medications or dosages.	To identify those associated with risk for electrolyte imbalance (e.g., including and not limited to diuretics, laxatives, certain antidepressants, corticosteroids).
Evaluate fluid intake and output, being aware whether client is currently on dialysis and, if so, what type. Measure and document 24-hour fluid deficit or excess.	Many factors (e.g., inability to take fluids for any reason; hemorrhage, excessive fluid resuscitation; vomiting, use of diuretics or dialysis) affect fluid balance, disrupting electrolyte transport, function, and excretion.
Suggest client keep a diary of foods/fluids ingested when electrolyte imbalances occur or are difficult to manage.	Review of actual intake may help identify hidden sources of electrolyte-containing foods, especially in ethnic diets that are not included on standard nutritional lists.
Assess mental status, noting client/caregiver report of change, such as altered attention span, recall of current events, and other cognitive functions.	Changes can be associated with electrolyte imbalance (e.g., commonly sodium).
Monitor heart rate and rhythm.	Tachycardia, bradycardia, and other dysrhythmias are associated with potassium, calcium, and magnesium imbalance.
Note presence/severity of anorexia; persistent vomiting, acute or chronic diarrhea; high nasogastric tube output; loss of bowel sounds.	Any disturbance of the gastrointestinal system carries with it the potential for electrolyte imbalances.
Evaluate motor strength and function, noting steadiness of gait, handgrip strength, and reactivity of reflexes.	Imbalances of sodium, potassium, calcium, magnesium, and phosphorus can impact neuromuscular function.
<b>Collaborative</b>	
Collaborate in the treatment of underlying conditions.	To prevent, limit, or treat effects if electrolyte imbalances caused by disease or organ dysfunction.
Consult with nutritionist/dietician to educate client/SO and to recommend or provide balanced nutrition, using best route for feeding as prescribed by condition. Restrict micronutrients (e.g., foods high in sodium, potassium glucose) as indicated, according to kidney function and comorbid conditions.	Obtaining and utilizing electrolytes and other minerals are dependent on client receiving them in a readily available form (including food and supplements via ingestion, enteral or parenteral feeding). If client with CKD is on dialysis (either peritoneal or hemodialysis), nutrients and electrolytes may be restricted or added depending on client's needs. Refer to CP: Renal dialysis for general and specific dietary concerns for client's needs.

### NURSING DIAGNOSIS: **risk for decreased Cardiac Output**

#### **Risk Factors May Include**

- Altered afterload—[e.g., systemic vascular resistance (SVR)]
- Altered preload—[e.g., decreased venous return]
- Alteration in heart rate, rhythm

**NURSING DIAGNOSIS:** **risk for decreased Cardiac Output** (continued)**Desired Outcomes/Evaluation Criteria—Client Will****Cardiac Pump Effectiveness NOC**

Maintain cardiac output as evidenced by blood pressure (BP) and heart rate/rhythm within client's usual range; peripheral pulses strong and equal with prompt capillary refill time.

Identify signs of cardiac decompensation, alter activities, and seek help appropriately.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Hemodynamic Regulation NIC</b>	
<i>Independent</i>	
Identify client at risk.	Client may have preexisting cardiac problems. But there is also potential for cardiac output issues to develop in client with CKD, particularly in later stages.
Assess presence and degree of hypertension: Monitor BP and note postural changes, such as sitting, lying, and standing.	Significant hypertension can occur because of disturbances in the renin-angiotensin-aldosterone system caused by renal dysfunction. Although hypertension is common, orthostatic hypotension may develop because of intravascular fluid deficit, response to effects of antihypertensive medications, or uremic pericardial tamponade.
Auscultate heart and lung sounds. Evaluate presence/degree of peripheral edema, vascular congestion, and reports of dyspnea.	S <sub>3</sub> /S <sub>4</sub> heart sounds with muffled tones, tachycardia, irregular heart rate, tachypnea, dyspnea, crackles, wheezes, and edema or jugular distention suggest heart failure (HF).
Investigate reports of chest pain, noting location, radiation, severity (0 to 10 or similar scale), and whether or not it is intensified by deep inspiration and supine position.	Although myocardial infarction (MI) is common, approximately half of clients on dialysis develop pericarditis, potentiating risk of pericardial effusion and tamponade.
Evaluate heart sounds, noting onset of friction rub, falling blood pressure, diminished or absent peripheral pulses, distended jugular veins, pallor, and obvious changes in mentation.	Can indicate cardiac tamponade, a medical emergency.
Assess activity level and response to activity.	Weakness can be attributed to heart failure and anemia.
<i>Collaborative</i>	
Monitor laboratory and diagnostic studies, such as the following:	
Electrolytes—potassium, sodium, calcium, magnesium; BUN/Cr	Imbalances can alter electrical conduction and cardiac function.
Chest x-rays	Useful in identifying developing cardiac failure and response to therapies.
Collaborate in treatment of underlying disease or conditions, where possible.	Slowing progression of CKD in early stages can be aided by interventions, such as controlling BP, managing diabetes, treating hyperlipidemia, and avoiding toxins such as NSAIDs, intravenous (IV) contrast dye, and aminoglycosides.
Administer medications, as indicated, for example:	Aggressive treatment of hypertension is needed to reduce SVR and aid in prevention of HF and MI. Note: Doses and dosing intervals of drugs that are excreted or metabolized renally are adjusted according to the residual GFR.
Statins, such as atorvastatin (Lipitor) and simvastatin (Zocor)	Statins may be used to treat elevated plasma cholesterol because of increased risk for coronary events, especially when GFR is below 60.
ACE inhibitors, such as enalapril (Vasotec), or angiotensin receptor blockers (ARBs), such as irbesartan (Avapro) and losartan (Cozaar)	These drugs may be prescribed not only to lower BP and reduce protein in the urine but also to slow the progression of kidney disease.

(continues on page 616)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Erythropoietin-stimulating agents (ESAs) such as Epojen, EPO or erythropoietin-stimulating proteins, such as somatropin (Nutropin) or darbepoetin alpha (Aranesp)	May be given to treat anemia associated with CKD when hemoglobin falls below 10 to improve oxygen-carrying capacity of circulating hemoglobin and reduce left ventricular strain. Note: ESA resistance, or hyporesponsiveness, can occur in client with CKD (not on dialysis) where the desired hemoglobin (Hb) concentration is not achieved despite higher than usual doses of ESAs (Berns, 2017).
Administer oxygen, as indicated.	Cardiac function can be improved with use of oxygen if client is severely anemic or metabolic acidosis and electrolyte abnormalities are causing dysrhythmias.
Prepare for renal replacement therapy (RRT), such as hemodialysis, peritoneal dialysis, or renal transplantation.	Reduction of uremic toxins and correction of electrolyte imbalances and fluid overload may limit or prevent cardiac manifestations, including hypertension and pericardial effusion.
Assist with pericardiocentesis, as indicated.	Accumulation of fluid within pericardial sac can compromise cardiac filling and myocardial contractility, impairing cardiac output and potentiating risk of cardiac arrest.

### NURSING DIAGNOSIS: risk for Activity Intolerance

#### Possibly Evidenced By

Circulatory problem [anemia]; physical deconditioning

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Activity Tolerance NOC

Participate in desired activities free of physiological signs of intolerance (e.g., pulse, respirations, and blood pressure remain within client's normal range).

ACTIONS/INTERVENTIONS	RATIONALE
<b>Energy Management NIC</b> <i>Independent</i> Note reports of increasing fatigue and weakness. Observe for tachycardia, pallor of skin and mucous membranes, dyspnea, and chest pain.	May reflect effects of anemia and cardiac response necessary to keep cells oxygenated.
Monitor level of consciousness (LOC) and behavior.	Anemia may cause cerebral hypoxia manifested by changes in mentation, orientation, and behavioral responses.
Evaluate response to activity and ability to perform tasks. Assist as needed and develop schedule for rest.	Anemia decreases tissue oxygenation and increases fatigue, which may require intervention, changes in activity, and rest.
<b>Collaborative</b> Monitor laboratory studies, such as RBCs, Hgb/Hct.	Uremia decreases production of erythropoietin in the bone marrow, thus depressing RBC production and survival time. In CKD, Hgb and Hct are usually low but tolerated (e.g., client may not be symptomatic until Hgb is below 7).
Administer fresh blood and packed red cells (PRCs), as indicated.	May be necessary when client is symptomatic with anemia. PRCs are usually given when client is experiencing fluid overload or receiving dialysis treatment. Washed RBCs are used to prevent hyperkalemia associated with stored blood.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Administer medications, as indicated, for example: Erythropoietin-stimulating agents such as preparations (Epogen, Procrit)	Stimulates the production and maintenance of RBCs, thus decreasing the need for transfusion. Note: Recent data showing increased risks of cardiovascular events with ESAs in CKD caused the Food and Drug Administration (FDA) to issue a black box warning about their use. Thus, clinicians have been advised to use the lowest possible ESA dose to reduce the need for transfusion and discontinue the ESA as quickly as possible (Alper et al, 2017; FDA, 2011).
Iron preparations, such as folic acid (Folvite) and cyanocobalamin (Rubesol-1000)	Useful in managing symptomatic anemia related to nutritional and dialysis-induced deficits. Note: Iron should not be given with phosphate binders because they may decrease iron absorption.

NURSING DIAGNOSIS: <b>risk for Bleeding</b>
<b>Possibly Evidenced By</b> Abnormal blood profile—decreased RBC production and survival, altered clotting functions (suppressed erythropoietin production or secretion) [Hypertension]
<b>Desired Outcomes/Evaluation Criteria—Client Will</b>
<b>Blood Loss Severity NOC</b> Experience no signs and symptoms of bleeding or hemorrhage. Maintain or demonstrate improvement in laboratory values.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Bleeding Precautions NIC</b>	
<b>Independent</b>	
Note client report of pain in specific areas and whether the pain is increasing and is diffuse or localized.	To determine possible sources of bleeding.
Assess vital signs, noting changes such as new or worsening hypertension. Investigate potential causes (especially if client has frequent nosebleeds).	Nosebleeds are a common occurrence with CKD (especially when on dialysis) and may be associated with hypertension and use of medications such as anticoagulants, immunosuppressants, and glucocorticoids.
Review medications periodically.	To identify those (prescriptions, OTC products, and herbals) that may cause, or exacerbate, bleeding.
Observe for oozing from venipuncture sites, bleeding, or ecchymotic areas following slight trauma, petechiae, and joint swelling or mucous membrane involvement—bleeding gums, recurrent epistaxis, hematemesis, melena, and hazy or red urine.	Bleeding can occur easily because of capillary fragility and altered clotting functions and may worsen anemia.
Test gastrointestinal (GI) secretions and stool for occult blood.	Mucosal changes and altered platelet function due to uremia may result in gastric mucosal erosion and GI hemorrhage.
Provide soft toothbrush and electric razor. Use smallest needle possible and apply prolonged pressure following injections or vascular punctures.	Reduces risk of bleeding and hematoma formation.
Protect at-risk client from trauma such as falls.	To reduce risk of injury causing overt or hidden hemorrhage.
<b>Collaborative</b>	
Monitor laboratory studies, such as the following:	
Platelet count, clotting factors	Suppression of platelet formation and inadequate levels of factors III and VIII impair clotting and potentiate risk of bleeding. Note: Bleeding may become intractable in ESRD.

(continues on page 618)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Prothrombin time (PT) level	Abnormal prothrombin consumption lowers serum levels and impairs clotting.
Collaborate in evaluating need for replacing blood (or specific components).	May be needed to replace losses or prevent complications associated with severe anemia.
Administer medications, as indicated, for example:	
Iron preparations, such as folic acid (Folvite) and cyanocobalamin (Rubesol-1000)	Useful in managing symptomatic anemia related to nutritional and dialysis-induced deficits. Note: Iron should not be given with phosphate binders because they may decrease iron absorption.
Cimetidine (Tagamet), ranitidine (Zantac), and antacids	May be given prophylactically to reduce or neutralize gastric acid and thereby reduce the risk of GI hemorrhage.

### NURSING DIAGNOSIS: risk for acute Confusion

#### Possibly Evidenced By

Metabolic abnormalities—electrolyte imbalances, increased blood urea nitrogen (BUN)/creatinine, azotemia, decreased

hemoglobin

Fluctuations in sleep-wake cycle

Infection

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Cognition NOC

Maintain or regain optimal level of mentation.

Identify ways to compensate for cognitive impairment and memory deficits.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Reality Orientation NIC</b>	
<i>Independent</i>	
Monitor for impairment in thinking ability, memory, and orientation. Note attention span.	Uremic syndrome's effect can begin with minor confusion or irritability and progress to altered personality, inability to assimilate information or participate in care. Awareness of changes provides opportunity for evaluation and intervention.
Ascertain from significant other (SO) client's usual level of mentation.	Provides comparison to evaluate development, progression, or resolution of impairment.
Provide SO with information about client's status.	Some improvement in mentation may be expected with restoration of more normal levels of BUN, electrolytes, and serum pH.
Provide quiet, calm environment and judicious use of TV, radio, and visitation.	Minimizes environmental stimuli to reduce sensory overload and confusion while preventing sensory deprivation.
Reorient to surroundings, person, and so forth. Provide calendars, clocks, and outside window.	Provides clues to aid in maintaining reality.
Present reality concisely and briefly, and do not challenge illogical thinking if present.	Confrontation potentiates defensive reactions and may lead to client mistrust and heightened denial of reality.
Communicate information and instructions in simple, short sentences. Ask direct, yes or no questions. Repeat explanations as necessary.	May aid in reducing confusion when present and increases possibility that communications will be understood and remembered.
Establish a regular schedule for expected activities.	Aids in maintaining reality orientation and may reduce fear and confusion.
Promote adequate rest and undisturbed periods for sleep.	Sleep deprivation may further impair cognitive abilities.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<b>Fluid/Electrolyte Management NIC</b> <i>Collaborative</i>	
Monitor laboratory studies, such as BUN/Cr, serum electrolytes, glucose level, and ABGs (PO <sub>2</sub> , pH).	Correction of imbalances can have profound effects on cognition.
Provide supplemental oxygen (O <sub>2</sub> ) as indicated.	Correction of hypoxia alone can improve cognition.
Avoid use of barbiturates and opiates.	Drugs normally detoxified in the kidneys will have increased half-life and cumulative effects, worsening confusion.
Prepare for dialysis.	Marked deterioration of thought processes may indicate worsening of azotemia and general condition, requiring prompt intervention to regain homeostasis.

**NURSING DIAGNOSIS:** risk for impaired Skin Integrity**Possibly Evidenced By**

Accumulation of toxins in the skin  
Impaired circulation (anemia with tissue ischemia) or sensation (peripheral neuropathy)  
Changes in skin turgor—edema  
Reduced activity, immobility

**Desired Outcomes/Evaluation Criteria—Client Will****Tissue Integrity: Skin and Mucous Membranes NOC**

Maintain intact skin.

**Risk Management NOC**

Demonstrate behaviors and techniques to prevent skin breakdown or injury.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Skin Surveillance NIC</b> <i>Independent</i>	
Inspect skin for changes in color, turgor, and vascularity. Note redness and excoriation. Observe for ecchymosis and purpura.	Indicates areas of poor circulation and early breakdown that may lead to decubitus formation and infection.
Monitor fluid intake and hydration of skin and mucous membranes.	Detects presence of dehydration or fluid overload that affects circulation and tissue integrity at the cellular level.
Inspect dependent areas for edema. Elevate legs, as indicated.	Edematous tissues are more prone to breakdown. Elevation promotes venous return, limiting venous stasis and edema formation.
Change position frequently, move client carefully, pad bony prominences with sheepskin, and use elbow and heel protectors.	Decreases pressure on edematous, poorly perfused tissues to reduce ischemia.
Provide soothing skin care, restrict use of soaps, and apply ointments or creams such as lanolin or Aquaphor.	Baking soda and cornstarch baths decrease itching and are less drying than soaps. Lotions and ointments may be desired to relieve dry, cracked skin.
Keep linens dry and wrinkle-free.	Reduces dermal irritation and risk of skin breakdown.
Investigate reports of itching.	Although dialysis has largely eliminated skin problems associated with uremic frost, itching can occur because the skin is an excretory route for waste products, such as phosphate crystals associated with hyperparathyroidism in ESRD.
Recommend client use cool, moist compresses to apply pressure to, rather than scratch, pruritic areas. Keep fingernails short; encourage use of gloves during sleep, add vinegar (acetic acid) to bath water, as needed.	Alleviates discomfort and reduces risk of dermal injury.
Suggest wearing loose-fitting cotton garments.	Prevents direct dermal irritation and promotes evaporation of moisture on the skin.

(continues on page 620)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<b>Collaborative</b> Provide foam or flotation mattress.	Reduces prolonged pressure on tissues, which can limit cellular perfusion, potentiating ischemia and necrosis.

### NURSING DIAGNOSIS: risk for impaired Oral Mucous Membrane

#### Possibly Evidenced By

Decrease in salivation; dehydration; fluid restrictions; inadequate nutrition; immunosuppression  
Treatment regimen; chemical irritation (conversion of urea in saliva to ammonia)

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Oral Health NOC

Maintain integrity of oral mucosa.

##### Risk Control NOC

Identify and initiate specific interventions to promote healthy oral mucosa.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Oral Health Maintenance NIC</b>	
<b>Independent</b>	
Inspect oral cavity: note moistness, character of saliva, presence of inflammation, ulcerations, and leukoplakia.	Provides opportunity for prompt intervention and prevention of infection.
Provide fluids throughout 24-hour period within prescribed limit.	Prevents excessive oral dryness from prolonged period without oral intake.
Offer frequent mouth care or rinse with 0.25% acetic acid solution. Provide gum, hard candy, or breath mints between meals.	Mucous membranes may become dry and cracked. Mouth care soothes, lubricates, and helps freshen mouth taste, which is often unpleasant because of uremia and restricted oral intake. Rinsing with acetic acid helps neutralize ammonia formed by conversion of urea.
Encourage good dental hygiene after meals and at bedtime. Recommend avoidance of dental floss.	Reduces bacterial growth and potential for infection. Dental floss may cut gums, potentiating bleeding.
Recommend client stop smoking and avoid lemon and glycerin products or mouthwash containing alcohol.	These substances are irritating to the mucosa and have a drying effect, potentiating discomfort.
Provide artificial saliva as needed, such as Ora-Lube.	Prevents dryness, buffers acids, and promotes comfort.

### NURSING DIAGNOSIS: ineffective Health Management

#### May Be Related To

Complexity of therapeutic regimen; complexity of healthcare system; insufficient knowledge of therapeutic regimen  
Economically disadvantaged

Perceived seriousness of condition, benefit or barrier; powerlessness

Insufficient social support

#### Possibly Evidenced By

Difficulty with prescribed regimen

Ineffective choices in daily living for meeting health goals

Unexpected acceleration of illness symptoms

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Self-Management: Kidney Disease NOC

Verbalize understanding of condition, disease process, and potential complications.

Verbalize understanding of therapeutic needs.

Correctly perform necessary procedures and explain reasons for the actions.

Demonstrate and initiate necessary lifestyle changes.

Participate in treatment regimen.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Teaching: Disease Process</b> <b>NIC</b>	
<i>Independent</i>	
Review disease process, prognosis, and future expectations. Educate regarding natural disease progression, different dialysis modalities, renal transplantation, and client's option to refuse or discontinue chronic dialysis.	Provides knowledge base from which client can make informed choices. Kidney failure choices depend on stage of disease and include doing no treatment, hemodialysis, peritoneal dialysis, and kidney transplantation. No matter which option is chosen, the client faces many lifestyle changes, including a complicated treatment plan involving several medications, diet and exercise modification, and appointments with numerous healthcare providers. Note: Client at stage 4 must be evaluated and prepared for renal replacement therapy—dialysis or transplantation.
Address client's and SO's feelings, concerns, and methods of dealing with situation. Offer compassionate listening and honest answers to questions. Refer to appropriate support resources.	Common reactions to diagnosis include disbelief, anxiety, anger at self and others, and mild to severe depression (including suicidal ideation). (Refer to CP: Psychosocial Aspects of Care; ND: risk for self-/other-directed Violence.)
Review dietary modifications or restrictions, including the following:	Dietary modifications are primarily required for person not on dialysis.
Phosphorus—milk, cheese, carbonated drinks, processed foods, poultry, corn, and peanuts	Dietary restrictions to control serum phosphorus, which are routinely recommended, are usually associated with a reduction in protein intake. This may lead to protein-energy wasting and poor survival. A better solution may be the use of specific nutritional supplements high in energy and protein content but lower in phosphorus (González-Parra et al, 2012).
Fluid, potassium, and sodium restrictions, when indicated	If fluid retention is a problem, client may need to restrict intake of fluid, such as previous day's output plus 500 mL for insensible losses, and restrict dietary potassium and sodium as prescribed. If fluid overload is present, diuretic therapy or dialysis will be part of the regimen. (Refer to CP: Acute Kidney Injury, ND: excess Fluid Volume.)
Discuss other nutritional concerns such as regulating protein intake according to level of renal function—generally 0.6 to 0.7 g/kg of body weight per day of good-quality protein, such as meat, chicken, fish, and eggs.	Metabolites that accumulate in blood derive almost entirely from protein catabolism; as renal function declines, proteins may be restricted proportionately. Too little protein can result in malnutrition. Note: Client on dialysis may not need to be as vigilant with protein intake.
Encourage adequate calorie intake, especially from carbohydrates in the nondiabetic client.	Spares protein, prevents wasting, and provides energy. Note: Use of special glucose polymer powders can add calories to enhance energy level without extra food or fluid intake.
Discuss drug therapy, including use of vitamin D, calcium supplements, and phosphate binders, such as calcium acetate (PhosLo), calcitriol (Caltrate), sevelamer (Renagel), and avoidance of magnesium antacids (Mylanta, Maalox, Gelusil).	Prevents serious complications, such as reducing phosphate absorption from the GI tract and supplying calcium to maintain normal serum levels, reducing risk of bone demineralization and fractures and tetany; however, use of aluminum-containing products should be monitored because accumulation in the bones potentiates osteodystrophy. Magnesium-containing products potentiate hypermagnesemia, which is already present late in chronic kidney disease and carries the risk of causing neurological problems (e.g., seizures). Note: Supplemental vitamin D may be required to facilitate calcium absorption.
Emphasize importance of reading all product labels—drugs and foods—and not taking medications (including over-the-counter products) without prior approval of healthcare provider.	It is difficult to maintain electrolyte balance when exogenous intake is not factored into dietary restrictions; for example, hypercalcemia can result from routine supplement use in combination with increased dietary intake of calcium-fortified foods and medications containing calcium.

(continues on page 622)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Instruct in (or review) BP or glucose monitoring at home and provide information on obtaining monitoring equipment, as indicated.	Because hypertension and poor glycemic control are high risk factors in kidney disease progression, self-monitoring and management are important. Also, hypertension is worsened by CRF, often requiring management with antihypertensive drugs, necessitating close observation of treatment effects, such as vascular response to medication.
Emphasize need for smoking cessation, if client smokes. Refer for nicotine medications and support resources.	Smoking increases renal vasoconstriction and exacerbates hypertension.
Review strategies to prevent constipation, including stool softeners, such as Colace, and bulk laxatives, such as Metamucil, but avoiding magnesium products (milk of magnesia).	Reduced fluid intake, changes in dietary pattern, and use of phosphate-binding products often result in constipation that is not responsive to nonmedical interventions. Use of products containing magnesium increases risk of hypermagnesemia.
Review measures to prevent bleeding or hemorrhage, such as use of soft toothbrush, electric razor, avoidance of constipation, forceful blowing of nose, strenuous exercise, or contact sports.	Reduces risks related to alteration of clotting factors and decreased platelet count.
Caution against exposure to external temperature extremes.	Peripheral neuropathy may develop, especially in lower extremities, because of effects of uremia and electrolyte/acid-base imbalances impairing peripheral sensation and potentiating risk of tissue injury.
Discuss role of fatigue in client's daily or desired activities. Advise establishing a routine exercise program within limits of individual ability and rest periods with activities. Instruct in energy conservation techniques.	Fatigue due to anemia, sleep disturbances, malnutrition, and failure of kidneys to clear toxins can greatly reduce client's tolerance for activity. At the same time, exercise is needed to maintain muscle tone and joint flexibility; reduces risks associated with immobility, including bone demineralization.
Address sexual concerns.	Physiological effects of uremia and antihypertensive therapy may impair sexual desire and performance.
Identify available resources such as nephrologist, nutritionist, and other specialists, as indicated. Emphasize necessity of medical and laboratory follow-up.	Close monitoring of renal function and electrolyte balance is necessary to adjust dietary prescription, treatment, and to make decisions about possible options such as dialysis or transplantation.
Discuss quality-of-life concerns, such as pros and cons of each treatment option, refusing or withdrawing dialysis, medical care advance directives, and durable power of attorney.	When kidney disease is chronic or end stage, client and SO may want to discuss issues with others, such as family, social worker, and religious counselor, and should have the opportunity to receive information to make informed choices.
Identify signs and symptoms requiring immediate medical evaluation, such as the following:	
Low-grade fever, chills, changes in characteristics of urine or sputum, tissue swelling or drainage, and oral ulcerations	Depressed immune system, anemia, and malnutrition all contribute to increased risk of infection.
Numbness or tingling of digits, abdominal and muscle cramps, carpopedal spasms, and pain and tenderness in extremities	Uremia and decreased absorption of calcium may lead to peripheral neuropathies. Note: Client is also at risk for development of thrombophlebotic complications.
Joint swelling or tenderness, decreased ROM, and reduced muscle strength	Hyperphosphatemia with corresponding calcium shifts from the bone may result in deposition of the excess calcium phosphate as calcifications in joints and soft tissues. Symptoms of skeletal involvement are often noted before impairment in organ function is evident.
Headaches, blurred vision, periorbital or sacral edema, and red eyes	Suggestive of development and poor control of hypertension and changes in eyes caused by calcium.
Provide client and family information resources, such as books, articles, and informational websites; the National Kidney Foundation; and the American Association of Kidney Patients.	Offers client and SO opportunity to obtain information, support, and sources of funding.

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

- **excess Fluid Volume**—compromised regulatory mechanism
- **Fatigue**—disease state, malnutrition, anemia, stress, depression
- **ineffective Health Management**—complexity of therapeutic regimen, decisional conflicts (e.g., client value system, health beliefs, cultural influences), powerlessness, economic difficulties, family conflict, social support deficit
- **Hopelessness**—deteriorating physiological condition, long-term stress, prolonged activity limitations

## RENAL DIALYSIS—GENERAL CONSIDERATIONS

### I. Procedure

- a. Process that substitutes for kidney function by removing excess fluid and accumulated endogenous or exogenous toxins
- b. Type of fluid and solute removal depends on the client's underlying pathophysiology, current hemodynamic status, vascular access, availability of equipment and resources, and healthcare providers' training.

### II. Indications

- a. Treatment for acute kidney injury (AKI) or chronic end-stage renal disease (ESRD)
- b. Indicated in AKI for (Spinner, 2014) the following:
  - i. Acid-base problems: such as severe acidosis
  - ii. Electrolyte problems: such as acute life-threatening hyperkalemia
  - iii. Intoxications: removal of toxins due to overdose of certain drugs (e.g., ethanol, some antiretroviral drugs, aminoglycosides, and antibiotics)
  - iv. Overload: (fluid)
  - v. Uremic symptoms caused by the inability to excrete nitrogenous wastes, parathyroid hormone, proteins, and other physiological substances in toxic levels
- c. Indicated in chronic kidney disease (Lameire & Biesen, 2010; Pradeep, 2017)
  - i. Pericarditis or pleuritis (urgent indication)
  - ii. Progressive uremic encephalopathy or neuropathy, with signs such as confusion, asterixis, myoclonus, wrist or foot drop, or, in severe cases, seizures (urgent indication)
  - iii. A significant tendency for bleeding attributable to uremia (urgent indication)
  - iv. Fluid overload unresponsive to diuretics
  - v. Life-threatening hypertension unresponsive to antihypertensive medications
  - vi. Persistent metabolic disturbances unresponsive to medical therapy (such as hyperkalemia, metabolic acidosis, hypercalcemia, hypocalcemia, and hyperphosphatemia)
  - vii. Failure to thrive; malnutrition

### III. Types

- a. Choice of dialysis is determined by three main factors:
  - i. Type of renal failure (acute or chronic)
  - ii. Client's particular physical condition
  - iii. Access to dialysis resources
- b. Two primary types of dialysis
  - i. Hemodialysis (HD)
    1. Requires placement of a venous access and a filtering machine removing the blood from the body, running it through a dialyzer, and then returning it to the body
    2. Conventional HD may be done three times a week over 3 to 4 hours, either at a facility or in the home, or daily dialysis may be done during the day or night hours, often at home.
  - ii. Peritoneal dialysis (PD)
    1. Requires a surgically placed abdominal catheter for infusing dialysate fluid into the peritoneal cavity for a predetermined dwell time and then draining it out
    2. Procedure may be carried out at home through gravity system or automated pump.

### IV. Statistics

- a. Morbidity: In 2014, approximately 468,000 individuals with ESRD received dialysis in the United States (414,180 receiving HD and 53,820 receiving PD). An additional 193,000 with ESRD received transplants as the initial mode of therapy (USRDS, 2015a).
- b. Mortality: Dialysis patients continue to have substantially higher mortality, and fewer expected remaining life years, when compared with the general population who have cancer, diabetes, or cardiovascular disease. However, the relative and absolute decline in mortality for dialysis patients in the past 15 years has been greater than for cancer, diabetes, or cardiovascular disease. In 2014, the adjusted mortality rate for dialysis patients was 166 per 1000 patient-years (USRDS, 2015a).
- c. Costs: In 2014, total Medicare payments for HD treatments were \$26.1 billion, while payments for PD were approximately \$3.6 billion (USRDS, 2015b).

## G L O S S A R Y

- Access:** Point on the body where a needle or catheter is inserted to gain entry to the bloodstream. Arteriovenous (AV) access is via graft, fistula, or central vein line.
- AV fistula:** Vascular access is made by joining an artery to a vein under the skin to make a bigger blood vessel.
- AV graft:** Soft plastic tube to join an artery and a vein under the skin.
- Dialysate:** Fluid used in both PD and HD that cleanses the blood and replaces needed electrolytes.
- Disequilibrium syndrome:** Nausea, vomiting, and hypertension, occasionally with convulsions, which develops within several hours after starting HD for renal failure; it is apparently caused by too rapid removal of urea from the extracellular fluid (ECF) compartment, with movement of water into cells and cerebral edema.
- Dry weight:** The lowest weight a patient can tolerate without the development of symptoms or hypotension.

Because physiological dry weight is that weight resulting from normal renal function, vascular permeability, serum protein concentration, and body volume regulation, dry weight in HD should, theoretically, be lower.

**Intradialytic parenteral nutrition (IDPN):** Involves infusing hyperalimentation fluids during the time of dialysis—through the vascular shunt or intraperitoneally—to normalize the amounts of albumin, glucose, and other nutrients in the bloodstream and to decrease the associated morbidity and mortality associated with protein-calorie malnutrition.

**Ultrafiltration:** Blood management method that removes noncellular water and low-molecular-weight solutes from anticoagulated blood through an extracorporeal (external from the body) filter.

## CARE SETTING

Primary focus is at the community level at the dialysis center, although inpatient acute stay may be required during initiation of therapy.

## RELATED CONCERNS

- Anemias—iron deficiency, anemia of chronic disease, pernicious, aplastic, hemolytic, page 541
- Heart failure: chronic, page 38
- Peritonitis, page 389
- Psychosocial aspects of care, page 835
- Sepsis/septic shock, page 772
- Total nutritional support: parenteral/enteral feeding, page 525

## CLIENT ASSESSMENT DATABASE

\*\*\*Refer to CPs: Acute Kidney Injury and/or Chronic Kidney Disease and End-Stage Renal Disease for assessment information.

### DIAGNOSTIC DIVISION MAY REPORT

### MAY EXHIBIT

#### DISCHARGE PLAN CONSIDERATIONS

- May require assistance with treatment regimen, transportation, activities of daily living (ADLs), homemaker and maintenance tasks, end-of life decisions, palliative care
- ♦ Refer to section at end of plan for postdischarge considerations.

## DIAGNOSTIC STUDIES

\*\*\*Studies and results are variable, depending on reason for dialysis, degree of kidney involvement, and client considerations, such as distance from treatment center, cognition, available support, and insurance options. Refer to CPs: Acute Kidney Injury and/or Chronic Kidney Disease and End-Stage Renal Disease for diagnostic studies.

**NURSING PRIORITIES**

1. Promote homeostasis and general well-being.
2. Maintain comfort.
3. Prevent complications.
4. Support client independence and self-care.
5. Provide information about disease process, prognosis, and treatment needs.

**DISCHARGE GOALS**

1. Fluid and electrolyte balance maximized.
2. Complications prevented or minimized.
3. Discomfort alleviated.
4. Dealing realistically with current situation; independent within limits of condition.
5. Disease process, prognosis, and therapeutic regimen understood.
6. Plan in place to meet needs after discharge.

This section addresses the general nursing management issues of client receiving some form of dialysis.

**NURSING DIAGNOSIS:** **imbalanced Nutrition: less than body requirements****May Be Related To**

Insufficient dietary intake, [increased metabolic demands]; inability to digest food/absorb nutrients (result of uremia, medication side effects; loss of peptides/amino acids; abdominal distention)

**Possibly Evidenced By**

Food intake less than recommended daily allowance; satiety immediately upon ingesting food; abdominal pain/cramping

Insufficient interest in food; perceived inability to ingest food; alterations in taste sensation; food [renal diet] aversion

Insufficient muscle tone; [decreased subcutaneous fat or muscle mass]

**Desired Outcomes/Evaluation Criteria—Client Will****Nutritional Status NOC**

Demonstrate stable weight or gain toward goal with normalization of laboratory values and no signs of malnutrition.

**ACTIONS/INTERVENTIONS****RATIONALE****Nutrition Therapy NIC***Independent*

Ascertain type and stage of kidney disease and note client's food intake and nutrition status before starting dialysis.  
Note type of dialysis client is (or will be) receiving (hemodialysis [HD] or peritoneal [PD]).

Client may present with widely varying nutrition needs (e.g., new diabetic with kidney failure, severe malnutrition related to long-term kidney disease, or be new to renal replacement therapy [RRT] and require dietary modifications). Each person's diet prescription is different, but the principal restrictions include protein, potassium, sodium, and phosphorus.

Monitor amount and type of ingested food. Calculate daily caloric intake prior to and periodically during dialysis.

Identifies nutritional deficits and diet therapy needs. Caloric intake during dialysis must be adequate for meeting daily metabolic demands, as well as for treating the malnutrition typically associated with ESRD.

Recommend client/significant other (SO) keep a food diary, including estimation of ingested calories, protein, and electrolytes of individual concern—sodium, potassium, chloride, magnesium, and phosphorus.

Helps client realize "big picture" and allows opportunity to alter dietary choices to meet individual desires within identified restrictions.

Note presence of nausea and anorexia.

These symptoms accompany accumulation of endogenous toxins and can alter or reduce food intake. Medical interventions may be needed to improve client's desire and ability to eat.

Encourage client to participate in menu planning.

May enhance oral intake and promote sense of control.

Recommend small, frequent meals. Schedule meals according to dialysis needs.

Smaller portions may enhance intake. Type of dialysis influences meal patterns; for instance, clients receiving HD might not be fed directly before or during procedure because this can alter fluid removal, and clients undergoing PD may be unable to ingest food while abdomen is distended with dialysate.

(continues on page 626)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Encourage use of herbs and spices such as garlic, onion, pepper, parsley, cilantro, and lemon.	Adds zest to food to help reduce boredom with diet, while reducing potential for ingesting too much potassium and sodium.
Suggest socialization during meals.	Provides diversion and promotes social aspects of eating.
Encourage frequent mouth care.	Reduces discomfort of oral stomatitis and metallic taste in mouth associated with uremia, which can interfere with food intake.
<b>Collaborative</b>	
Perform complete nutrition assessment, using appropriate anthropometric and nutrition tools, consisting of laboratory studies (e.g., total proteins, glucose, micronutrients), comparison of initial weight with both usual body weight and percent of ideal body weight, and review of food diaries.	Assesses adequacy of nutrient utilization and points to diet therapy needs. Note: Malnutrition is often present to some degree in any client with severe or chronic kidney disease. Studies have shown that the presence of malnutrition prior to initiation of dialysis is strongly predictive of increased mortality (Kalantar-Zadeh & Fouque, 2017).
Refer to nutritionist or dietitian to develop diet appropriate to client's needs.	It is necessary to develop a highly individual dietary program to meet needs within specific limitations. Nutrition-related concerns include maintenance of acceptable weight and serum proteins, prevention of renal osteodystrophy (defective bone development), and reduction of cardiovascular risks associated with protein energy malnutrition, electrolyte and micronutrient deficiencies (Kalantar-Zadeh & Fouque, 2017).
Provide a balanced diet with prescribed calories and high-quality protein.	The client on hemodialysis (HD) may not be calorie limited. However, in peritoneal dialysis (PD), some calories come from dialysate solution (contains dextrose), thus reducing client's calories requirements from food (Swaford, n.d.). Protein intake in a clinically stable hemodialysis client is currently recommended to be 1.2 to 1.4 g/kg body weight/d, 60% of which should come from sources high in biological value (e.g., fish, poultry eggs) (Kalantar-Zadeh & Fouque, 2017; Swaford, n.d.).
Restrict sodium (usually to 2 g or less/d) to manage body fluids and potassium as prescribed. Avoid bacon, ham, other processed meats and foods, orange juice, and tomato soup.	These electrolytes can quickly accumulate, causing fluid retention, weakness, and potentially lethal cardiac dysrhythmias. Note: Potassium removal is more efficient on PD because the treatment occurs daily. A typical daily goal for PD patients is 3000 to 4000 mg of potassium (Swaford, n.d.).
Limit foods high in calcium and phosphorus, as indicated.	Mineral and bone disorder in CKD occurs when damaged kidneys and abnormal hormone levels cause calcium and phosphorus to be out of balance. This disorder commonly occurs in people with CKD and affects most people receiving dialysis. Note: It has been recommended that (in general) calcium intake should be limited to 2000 mg/d and phosphorus limited to 800 to 1000 mg/d while on either HD or PD (National Institute for Diabetes and Digestive and Kidney Diseases [NIDDK], 2015; Swaford, n.d.).
Administer multivitamins, including folic acid; vitamins B <sub>6</sub> , C, and D; and iron supplements, as indicated.	Replaces vitamin and mineral deficits resulting from malnutrition, anemia, or loss during dialysis.
Administer parenteral supplements, as indicated, or interdialytic parenteral nutrition (IDPN), as necessary.	Parenteral nutrition may be given to provide nutrients only if oral intake is insufficient to prevent malnutrition and enteral feeding is contraindicated. IDPN may be required in client who (1) continues to lose weight, (2) has very low serum albumin despite oral supplementation, or (3) when parenteral route is unavailable or contraindicated. Note: IDPN is convenient because it is delivered during dialysis and is beneficial in some clients. However, only about 70% of the nutrients are actually delivered to the patient.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Monitor laboratory studies, for example:	because of loss into the dialysate. Recent treatment guidelines and reimbursement schedules indicate that use of IDPN should be limited and initiated only after aggressive attempts at enteral feeding (Beddhu et al, 2017).
Comprehensive metabolic panel (e.g., glucose, total proteins, calcium, electrolytes)	Provides information about the current status of a person's metabolism and nutrition status. Abnormal results, especially combinations of abnormal results, can indicate a dietary problem that needs to be addressed.
Hemoglobin (Hgb), red blood cell (RBC), and iron levels	Anemia is the most pervasive complication affecting energy levels in ESRD.
Administer medications, as appropriate, for example:	
Antiemetics, such as prochlorperazine (Compazine)	Reduces stimulation of the vomiting center.
Histamine blockers, such as famotidine (Pepcid)	Gastric distress is common and may be a neuropathy-induced gastric paresis. Hypersecretion can cause persistent gastric distress and digestive dysfunction.
Hormones and supplements as indicated, such as erythropoietin (EPO, Epogen) and iron infusions or oral supplements (e.g., Feosol, Ferrex 150)	Although EPO is given to increase numbers of RBCs, it is not effective without iron supplementation.
Insert and maintain nasogastric (NG) or enteral feeding tube, if indicated.	May be necessary when persistent vomiting occurs or when enteral feeding is desired.

### NURSING DIAGNOSIS: risk for impaired Skin Integrity

#### Possibly Evidenced By

Chemical injury agent (e.g., uremia; phosphorus); pharmaceutical agent(s) [and drug allergies]  
Alteration in skin turgor/fluid volume  
Inadequate nutrition; alteration in metabolism  
Impaired circulation; alteration in sensation

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Tissue Integrity: Skin & Mucous Membranes NOC

Maintain structural intactness of epidermis and dermis.

##### Risk Control NOC

Participate in prevention measures.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Skin Surveillance NIC</b>	
<i>Independent</i>	
Perform routine skin inspections in at-risk client, documenting observed changes. Ask client about skin sensations.	Skin conditions that can affect client on dialysis include (1) itching (pruritus) from high level of phosphorus; (2) dry skin (xerosis)—CKD-related changes in sweat and oil glands; and (3) skin discoloration (hyperpigmentation) due to retention of urochromes normally excreted by kidneys (DaVita Kidney Care Staff, n.d.).
Assess activity limitations, noting presence and degree of restriction or ability.	Influences choice of interventions. Note: Fear of or real danger of dislodging dialysis lines or catheter may cause client to be reluctant to initiate movement.
Encourage frequent change of position when on bedrest or chair rest; support affected body parts and joints with pillows, rolls, sheepskin, and elbow and heel pads, as indicated.	Decreases discomfort, maintains muscle strength and joint mobility, enhances circulation, and prevents skin breakdown.

(continues on page 628)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Provide and encourage soothing skin care (e.g., bathing with soap for sensitive skin; applying high-water content gel, lotion, or cream right after bath while skin is still damp; avoiding alcohol-based lotions).	Helps to maintain softer and more elastic skin, making it more protective against breakdown.
Keep body pressure points and skin folds clean and dry. Keep bed linens dry and wrinkle-free.	Reduces skin irritation and likelihood of breaking down/injury at pressure points. Note: Dry bed linens may be of special importance in client with uremic pruritus, which is often generalized and especially bothersome when it affects the back.
Instruct in and assist with active and passive range-of-motion (ROM) exercises.	Promotes circulation, maintains joint flexibility, prevents contractures, and aids in reducing muscle tension. Note: A high level of phosphorus may cause calcium-phosphorus crystals to build up in the joints, muscles, and other body organs, leading to bone and joint pain. To avoid these risks, client may be prescribed a phosphate binder (e.g., calcium acetate [PhosLo]).
Encourage client to be up and about as much as possible. Institute a planned activity or exercise program as appropriate, with client's input.	Improves systemic circulation (good for the skin) and increases client's energy and sense of well-being. Note: Recent studies report findings of significant beneficial effects of various exercise interventions in CKD patients (including those on dialysis), positively impacting muscular functioning, walking capacity, cardiovascular function, and quality of life (Heiwe & Jacobson, 2014).

**Collaborative**

Provide foam, water, or air flotation mattress or soft chair cushion.

Reduces tissue pressure and may enhance circulation, thereby reducing risk of dermal ischemia and breakdown.

### NURSING DIAGNOSIS: **Self-Care deficit (specify)**

#### May Be Related To

Weakness, fatigue; decrease in motivation

Pain, discomfort

Alteration in cognitive functioning; perceptual disorders (accumulated toxins)

#### Possibly Evidenced By

Impaired inability to perform ADLs

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Self-Care Status NOC

Performs ADLs within level of own ability and constraints of the illness.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Self-Care Assistance NIC</b>	
<i>Independent</i>	
Determine client's physical ability to participate in self-care activities (scale of 0 to 4). Note degree of fatigue, cognitive and emotional factors that may impact self-care, and presence/location/intensity of pain.	Underlying condition dictates level of deficit, affecting choice of interventions. Note: Multiple other factors associated with CKD (e.g., fatigue, cognitive impairment, pain, depression, lack of motivation or support) also have a major impact on the client's abilities.
Active-listen client's/SOs concerns. Participate in working on solutions and mutual goal setting.	Exhibits regard for client's values and beliefs, clarifies barriers to participation in self-care, provides opportunity for problem-solving, and provides support.
Provide assistance with activities as necessary. Encourage client/SO to participate in planning and decision making of needed/desired activities.	Meets immediate needs while supporting client participation and independence.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Encourage use of energy-saving techniques: sitting, not standing; using shower chair; resting between activities; and doing tasks in small increments.	Conserves energy, reduces fatigue, and enhances client's ability to perform tasks.
Recommend scheduling activities to allow client sufficient time to accomplish tasks to fullest extent of ability.	Unhurried approach reduces frustration and promotes client participation, enhancing self-esteem.
<b>Collaborative</b> Collaborate with PT/OT to evaluate individual abilities and assistive devices as needed.	Modified exercise program aids in maintaining muscle strength and appropriate use of assistive devices supports independence.
Provide analgesics as indicated.	Alleviation of discomforts/pain can give client energy and motivation to address needed tasks.

### NURSING DIAGNOSIS: risk for Constipation

#### Possibly Evidenced By

Eating habit change; insufficient food/fluid intake  
Decrease in gastrointestinal motility  
Electrolyte imbalance

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Bowel Elimination NOC

Maintain usual or improved bowel function.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Constipation/Impaction Management NIC</b>	
<b>Independent</b>	
Auscultate bowel sounds. Note consistency and frequency of bowel movements (BMs) and presence of abdominal distention.	Decreased bowel sounds, passage of hard-formed or dry stools suggest constipation and requires ongoing intervention to manage.
Review current medication regimen.	Side effects of some treatment-related drugs, such as iron products and some antacids, may compound problem.
Ascertain usual dietary pattern and food choices.	Although restrictions may be present, thoughtful consideration of menu choices can aid in controlling problem.
Suggest adding fresh fruits, vegetables, and fiber to diet within restrictions, when indicated.	Provides bulk, which improves stool consistency and reduces incidence of constipation. Note: The National Academy of Sciences Institute of Medicine noted that fiber prompts the absorption of calcium in person with CKD (thus improving calcium balance and bone mineral density) and helps control both high blood pressure and high blood sugar levels (Kidney Cares Community, 2013).
Encourage or assist with ambulation, and exercise program when able.	Activity may stimulate peristalsis, promoting return to normal bowel activity.
Provide privacy at bedside commode and bathroom.	Promotes psychological comfort needed for elimination.
<b>Collaborative</b>	
Administer stool softeners, such as docusate sodium (Colace), or bulk-forming laxatives, such as psyllium (Metamucil), as appropriate.	Produces a softer, more easily evacuated stool.

## NURSING DIAGNOSIS: risk for acute Confusion

### Possibly Evidenced By

Impaired metabolic functioning—electrolyte imbalances, increased blood urea nitrogen (BUN)/creatinine, azotemia, decreased hemoglobin; malnutrition  
Alteration in sleep-wake cycle; pain; impaired mobility

### Desired Outcomes/Evaluation Criteria—Client Will

#### Cognition NOC

Maintain or regain usual or improved level of mentation.  
Recognize changes in thinking and behavior and demonstrate behaviors to prevent or minimize changes.

### ACTIONS/INTERVENTIONS

### RATIONALE

#### Delirium Management NIC

##### Independent

Assess for behavioral changes or change in level of consciousness (LOC)—disorientation, lethargy, decreased concentration, memory loss, and altered sleep pattern.

May indicate level of uremic toxicity, developing complication of dialysis such as disequilibrium syndrome, and need for further assessment and intervention.

Keep explanations simple and reorient frequently as needed.  
Provide “normal” day or night lighting patterns, clock, and calendar.

Improves reality orientation.

Provide a safe environment and providing presence (someone with client) during procedure, as appropriate.

Prevents client injury and inadvertent removal of dialysis lines or catheter if client is confused.

Drain peritoneal dialysate promptly at end of specified equilibration period.

Prompt outflow will decrease risk of hyperglycemia or hyperosmolar fluid shifts affecting cerebral function.

Investigate reports of headache, associated with onset of dizziness, nausea, and vomiting, and note onset of progressive confusion, agitation, hypotension, tremors, or seizure activity.

May reflect development of disequilibrium syndrome (DDS), a neurological phenomenon, which can occur near completion of or following HD, particularly when client is first starting dialysis therapy. It is thought to be associated with cerebral edema (Mailloux, 2016).

##### Collaborative

Monitor lab studies such as:

BUN/Cr and serum glucose levels, determine urea reduction ratio (URR)

Follows progression or resolution of azotemia. Pre- and postdialysis BUN levels are used to determine efficacy of procedure. Also, urea reduction ratio (URR) of at least 60% to 65% (measured monthly) is considered a desirable response to dialysis (NIDDK, 2014).

Aluminum level, as indicated

Elevation may warn of impending cerebral involvement or dialysis dementia.

Alternate or change dialysate concentrations according to protocol, and add insulin, as indicated.

Hyperglycemia may develop secondary to glucose crossing peritoneal membrane and entering circulation. May require initiation of insulin therapy.

Administer normal saline intravenously (IV), as appropriate.

Volume restoration may be sufficient to reverse effects of disequilibrium syndrome.

Administer medication, as indicated, such as phenytoin (Dilantin), mannitol (Osmotrol), and barbiturates.

If disequilibrium syndrome occurs during dialysis, medication may be needed to control seizures in addition to a change in dialysis prescription or discontinuation of therapy.

## NURSING DIAGNOSIS: Anxiety [specify level]

### May Be Related To

Situational crisis; stressors; threat of death

Threat to current status (e.g., change in health status, role functioning, or socioeconomic status)

**NURSING DIAGNOSIS:** **Anxiety [specify level]** (continued)**Possibly Evidenced By**

Worried about change in life event  
 Increase in tension; apprehensiveness; uncertainty, fear; hypervigilance; insomnia  
 Sympathetic stimulation; alteration in attention/concentration; diminished ability to problem solve

**Desired Outcomes/Evaluation Criteria—Client Will****Anxiety Self-Control NOC**

Verbalize awareness of feelings and reduction of anxiety to a manageable level.  
 Demonstrate problem-solving skills and effective use of resources.  
 Appear relaxed and able to rest and sleep appropriately.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Anxiety Reduction NIC</b>	
<i>Independent</i>	
Assess level of concern of both client and SO. Note signs of denial, depression, or narrowed focus of attention.	Helps determine the kind of interventions required.
Explain procedures and care as delivered. Repeat explanations frequently, as needed. Provide information in multiple formats, including pamphlets and films.	Fear of unknown is lessened by information and knowledge and may enhance acceptance of permanence of ESRD and necessity for dialysis. Alteration in thought processes and high levels of anxiety or fear may reduce comprehension, requiring repetition of important information. Note: Uremia can impair short-term memory, requiring repetition or reinforcement of information provided.
Acknowledge normalcy of feelings in this situation.	Knowing feelings are normal can allay fear that client is losing control.
Provide opportunities for client and SO to ask questions and verbalize concerns.	Creates feeling of openness and cooperation and provides information that will assist in problem identification and solving.
Encourage SO to participate in care, as able and desired.	Involvement promotes sense of sharing, strengthens feelings of usefulness, provides opportunity to acknowledge individual capabilities, and may lessen fear of the unknown.
Acknowledge concerns of client and SO.	Prognosis and possibility of need for long-term dialysis and resultant lifestyle changes are major concerns for this client and those who may be involved in future care.
Point out current positive indicators of treatment—improvement in laboratory values, stable BP, or lessened fatigue.	Promotes sense of progress in an otherwise chronic process that seems endless while client still is experiencing physical deterioration and depression.
<i>Collaborative</i>	
Arrange for visit to dialysis center and meeting with another dialysis client, as appropriate.	Interaction with others who have encountered similar problems may assist client and SO to work toward acceptance of chronic condition and focus on problem-solving activities.
Address financial considerations. Refer to appropriate resources.	Treatment for kidney failure is expensive, although Medicare and other health insurance programs pay much of the cost. Loss of income/need for home care and so on increase financial worries.

**NURSING DIAGNOSIS:** **disturbed Body Image****May Be Related To**

Illness; treatment regimen  
 Alteration in body function, self-perception, cognitive functioning

(continues on page 632)

**NURSING DIAGNOSIS:** **disturbed Body Image** (continued)**Possibly Evidenced By**

Perceptions that reflect an altered view of one's body appearance; negative feeling about body (e.g., feelings of helplessness, powerlessness)  
Focus on past function; refusal to acknowledge change; preoccupation with change  
Change in lifestyle, social involvement  
Extension of body boundary (incorporates environmental objects—dialysis equipment)

**Desired Outcomes/Evaluation Criteria—Client Will****Body Image NOC**

Identify feelings and methods for coping with negative perception of self.  
Verbalize acceptance of body function/change in health status.

**Psychosocial Adjustment: Life Change NOC**

Demonstrate adaptation to changes and events that have occurred, as evidenced by setting realistic goals and active participation in care and life in general.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Body Image Enhancement NIC</b> <i>Independent</i>	
Assess level of client's knowledge about condition and treatment and anxiety related to current situation.	Identifies extent of problem or concern and necessary interventions.
Discuss meaning of loss and change to client.	Many clients and their families have difficulty dealing with changes in life and role performance as well as the client's loss of ability to control own body.
Note withdrawn behavior, ineffective use of denial, or behaviors indicative of overconcern with body and its functions. Investigate reports of feelings of depersonalization or the bestowing of humanlike qualities on machinery.	Indicators of developing difficulty handling stress of what is happening. Note: Client may feel tied to and controlled by the technology central to his or her survival, even to the point of extending body boundary to incorporate dialysis equipment.
Assess for use of addictive substances, primarily alcohol, other drugs, and self-destructive or suicidal behavior.	May reflect dysfunctional coping and attempt to handle problems in an ineffective manner.
Determine stage of grieving. Note signs of severe or prolonged depression.	Identification of grief stage client is experiencing provides guide to recognizing and dealing appropriately with behavior as client and SO work to come to terms with loss and limitations associated with condition. Prolonged depression may indicate need for further intervention.
Acknowledge normalcy of feelings.	Recognition that feelings are to be expected helps client accept and deal with them more effectively.
Encourage verbalization of personal and work conflicts that may arise. Actively listen to concerns.	Helps client identify problems and problem-solve solutions. Note: Home dialysis may provide more flexibility and enhance sense of control for clients who are appropriate candidates for this form of therapy.
Determine client's role in family constellation and client's perception of expectation of self and others.	Long-term and permanent illness or disability alters client's ability to fulfill usual role(s) in family and work setting. Unrealistic expectations can undermine self-esteem and affect outcome of illness.
Recommend SO treat client normally and not as an invalid.	Conveys expectation that client is able to manage situation and helps maintain sense of self-worth and purpose in life.
Assist client to incorporate disease management into lifestyle.	Necessities of treatment assume a more normal aspect when they are a part of the daily routine.
Identify strengths, past successes, and previous methods client has used to deal with life stressors.	Focusing on these reminders of own ability to deal with problems can help client deal with current situation.
Help client identify areas over which he or she has some measure of control. Provide opportunity to participate in decision-making process.	Provides sense of control over seemingly uncontrollable situation, fostering independence.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<b>Collaborative</b> Recommend participation in local support group.	Reduces sense of isolation as client learns that others have been where client is now. Provides role models for dealing with situation, problem-solving, and “getting on with life.” Reinforces that therapeutic regimen can be beneficial.
Refer to healthcare and community resources, such as social service, vocational counselor, and psychiatric clinical nurse specialist.	Provides additional assistance for long-term management of chronic illness and change in lifestyle.

### NURSING DIAGNOSIS: risk for ineffective Health Management

#### Possibly Evidenced By

Difficulty managing complex treatment regimen/navigating complex healthcare systems  
 Perceived seriousness of condition, susceptibility, benefit or barriers  
 Excessive demands; family conflict; decisional conflicts; powerlessness  
 Economically disadvantaged; insufficient social support

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Self-Management: Kidney Disease NOC

Verbalize understanding of condition and relationship of signs and symptoms of the disease process and potential complications.  
 Verbalize understanding of therapeutic needs.  
 Correctly perform necessary procedures and explain reasons for actions.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Teaching: Disease Process NIC</b> <b>Independent</b> Note level of anxiety or fear and alteration of thought processes. Time teaching appropriately.	These factors directly affect ability to access and use knowledge. In addition, during the dialysis procedure, client’s cognitive function may be impaired, and clients themselves state that they feel “fuzzy.” Therefore, learning may not be optimal during this time.
Review particular disease process, prognosis, and potential complications in clear concise terms, periodically repeating and updating information, as necessary.	Providing information at the level of the client’s and SO’s understanding will reduce anxiety and misconceptions about what client is experiencing.
Encourage and provide opportunity for questions.	Enhances learning process, promotes informed decision making, and reduces anxiety associated with the unknown.
Acknowledge that certain feelings and patterns of response are normal during course of therapy.	Client and SO may initially be hopeful and positive about the future, but as treatment continues and progress is less dramatic, they can become discouraged and depressed, and conflicts of dependence versus independence may develop.
Emphasize necessity of reading all product labels—food, beverage, and over-the-counter (OTC) drugs—and not taking medications or herbal supplements without checking with healthcare provider.	It is difficult to maintain electrolyte balance when exogenous intake is not factored into dietary restriction; for example, hypercalcemia can result from routine supplement use in combination with increased dietary intake of calcium-fortified foods and medicines.
Emphasize importance of adhering to medication schedule required for the client’s specific form of renal disease, timing of dialysis, and properties of the individual medications.	This is necessary to ensure that therapeutic levels of the drugs are reached and that toxic levels are avoided.
Discuss significance of maintaining nutritious eating habits, preventing wide fluctuation of fluid and electrolyte balance, and avoidance of crowds or people with infectious processes.	Depressed immune system, presence of anemia, invasive procedures, and malnutrition potentiate risk of infection.

(continues on page 634)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Instruct client about ESOs (e.g., epoetin [Epogen], darbepoetin [Aransep]), when used. Have client or SO demonstrate ability to administer and state adverse side effects and healthcare practices associated with this therapy.	Used for the management of the anemia associated with CRF and ESRD. Contraindications may include adverse side effects such as polycythemia, increased clotting, failure to administer correctly or have appropriate follow-up.
Identify healthcare and community resources, such as dialysis support group, social services, and mental health clinic.	Knowledge and use of these resources assist client and SO to manage care more effectively. Interaction with others in similar situation provides opportunity for discussion of options and making informed choices, including stopping dialysis or renal transplantation.
<b>Teaching: Procedure/Treatment NIC</b> Discuss procedures and purpose of dialysis in terms understandable to client. Repeat explanations as required.	A clear understanding of the purpose, process, and what is expected of client and SO facilitates their cooperation with regimen and may enhance outcomes.
Instruct client and SO in home dialysis, as indicated:	Home dialysis is associated with better outcomes in general and better survival rates as dialysis is usually performed 5 to 7 days/week and is more intensive. This decreases fluctuations in fluid, solute, and electrolyte balance, more closely mimicking renal function. However, specific criteria for client and SO participation and training, home resources, and professional oversight must be met in order to consider this option.
Operation and maintenance of equipment (including vascular shunt), sources of supplies	Information diminishes anxiety of the unknown and provides opportunity for client to be knowledgeable about own care.
Aseptic or clean technique	Prevents contamination and reduces risk of infection.
Self-monitoring of effectiveness of procedure	Provides information necessary to evaluate effects of therapy and need for change.
Management of potential complications	Reduces concerns regarding personal well-being; supports efforts at self-care.
Provide contact information for dialysis support persons.	Readily available support person can answer questions, troubleshoot problems, and facilitate timely medical intervention, when indicated, reducing risk and severity of complications. Note: Home dialysis clients usually are monitored by conventional dialysis center or interdisciplinary team.
Identify sources for supplies at home and when away from home.	Home dialysis clients are often capable of travel, even overseas, with proper preplanning and support.

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

- **Fatigue**—disease state, malnutrition, altered body chemistry, stress, depression
- **excess Fluid Volume**—compromised regulatory mechanism
- **risk for Infection**—invasive procedures, decreased hemoglobin, chronic disease, malnutrition
- **ineffective Health Management**—complexity of therapeutic regimen, economic difficulties, decisional conflicts; excessive demands made on individual and family
- **risk for caregiver Role Strain**—illness severity of care receiver, caregiver is spouse, presence of situational stressors, complexity/amount/duration of caregiving required

## PERITONEAL DIALYSIS (PD)

### I. Procedure

- a. Requires a surgically placed abdominal catheter and uses the peritoneum to filter toxins and excess fluid from the body
- b. Fluid removal is controlled by adjusting the dextrose concentration in the dialysate (e.g., 1.5%, 2.5%, 4.25%) to create an osmotic gradient for water with higher dextrose concentrations and more frequent exchanges increasing the rate of fluid removal.
- c. May be preferred over hemodialysis because it uses a simpler technique and provides more gradual physiological changes
- d. Long-term PD typically calls for three to four exchanges a day, each with a dwell time of 4 to 6 hours, and a long (8- to 10-hour) dwell time at night.

### II. Types (NIDDK, 2016b)

- a. Continuous ambulatory peritoneal dialysis (CAPD)
  - i. Most commonly used type of long-term PD, allowing client to manually manage the procedure at home with bag and gravity flow
  - ii. Some clients experience problems with the long overnight dwell time because, as dextrose in the solution crosses into body, it becomes glucose and starts to draw fluid from the peritoneal cavity back into the body,

thereby reducing the efficiency of the exchange and requiring a mini-cycler machine during the night.

### b. Automated peritoneal dialysis (APD)

- i. Continuous cycler-assisted peritoneal dialysis (CCPD)
  1. Uses a machine (cycler) to fill and empty the abdomen three to five times during the night while the person sleeps. In the morning, the last fill remains in the abdomen with a dwell time that lasts the entire day. May be a method of choice for younger individuals engaged in work activities.
  2. A combination of APD and CAP may be needed under certain client conditions (e.g., client is over the weight restrictions; client's peritoneum filters wastes too slowly).

### c. Statistics

- a. Morbidity: In 2014, approximately 129,450 Americans received PD (USRDS, 2015a).
- b. Mortality: In 2014, adjusted mortality rate was 157 for peritoneal dialysis patients, per 1000 patient-years (USRDS, 2015c).
- c. Costs: In 2014, Medicare payments for outpatient PD were approximately \$3.6 billion. Per patient per year costs for all PD patients averaged \$73,612 (USRDS, 2015b).

### G L O S S A R Y

**Automated peritoneal dialysis (APD):** Uses a machine to control the time of exchanges; warm, infuse, and drain the used solution at preset intervals; and fill the peritoneal cavity with new solution.

**Continuous ambulatory peritoneal dialysis (CAPD):** Uses three to five cycles daily and one long overnight dwell time, 7 days/week.

**Continuous cycler-assisted peritoneal dialysis (CCPD):** Mechanical device cycles shorter dwell times during the night (three to six cycles) with one 8-hour dwell time during daylight hours, thus increasing the client's independence.

**Cycle:** The infusion and drainage of a specific volume of peritoneal dialysis solution. The dwell time may vary from a few minutes to several hours.

**Cycler:** Machine used to infuse and drain dialysate from the peritoneal cavity.

**Dialysate (dialysis fluid):** A mixture of water, electrolytes, and dextrose. Electrolyte levels in dialysate are propor-

tioned to ensure that the levels in the blood remain within physiological range. Waste products, such as BUN and creatinine, are not present in the dialysate and will readily move out of the blood into the dialysis fluid.

**Nocturnal intermittent peritoneal dialysis (NIPD):** Similar to CCPD, except the number of overnight exchanges is greater (six to eight) and no exchange is performed during the day.

**Peritoneal dialysis (PD):** Treatment for both acute kidney injury (AKI) and end-stage renal disease (ESRD) using the peritoneum as the semipermeable membrane permitting transfer of nitrogenous waste products, toxins, and fluid from the blood into a dialysate solution.

**Ultrafiltrate:** The net amount of fluid resulting when the original volume of the dialysate used for a certain dwell is subtracted from the volume of the drained dialysate (effluent-infused dialysate = ultrafiltrate).

### NURSING DIAGNOSIS: risk for excess Fluid Volume

#### Possibly Evidenced By

Compromised regulatory mechanism (e.g., inadequate osmotic gradient of dialysate; fluid retention—malpositioned, kinked, or clotted internal catheter)

Excess fluid intake—oral (PO) or intravenous (IV)

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Fluid Overload Severity NOC

Demonstrate dialysate outflow exceeding or approximating infusion.

Experience no rapid weight gain, edema, or pulmonary congestion.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Peritoneal Dialysis Therapy NIC</b>	
<b>Independent</b>	
Monitor client's oral fluid intake (and educate client about fluid management) during and between dialysis.	Fluid overload is not usually a big problem with PD because procedure is performed every day. The exception may be if client is not following kidney diet or misses a dialysis session.
Maintain a record of inflow and outflow volumes and cumulative fluid balance.	In most cases, the amount drained should equal or exceed the amount instilled. A positive balance with more fluid in than out indicates need for further evaluation.
Record serial weights, compare with intake and output (I&O) balance. Weigh client when abdomen is empty of dialysate, providing a consistent reference point.	Serial body weights are an accurate indicator of fluid volume status. A positive fluid balance with an increase in weight indicates fluid retention.
Turn from side to side, elevate the head of the bed, and apply gentle pressure to the abdomen.	May enhance outflow of fluid when catheter is malpositioned or obstructed by the peritoneal omentum.
Note abdominal distention associated with poor dialysate outflow, decreased bowel sounds, changes in stool consistency, and reports of constipation.	Bowel distention or constipation may impede outflow of effluent. Note: Constipation, the most common cause of poor outflow, is associated with several factors (e.g., lack of fiber in diet, fluid restrictions, peritoneal catheter malfunction or occasionally peritonitis), which can result in dialysis failure. (Refer to CP: Renal Dialysis: general considerations, ND: risk for Constipation.)
Monitor blood pressure (BP) and pulse, noting escalating hypertension, shortness of breath, neck vein distention, and peripheral edema; measure central venous pressure (CVP), if available.	Elevations indicate hypervolemia. Assess heart and breath sounds, noting S <sub>3</sub> and crackles and rhonchi. Fluid overload may potentiate heart failure (HF) or pulmonary edema.
Evaluate development of tachypnea, dyspnea, and increased respiratory effort. Drain dialysate and notify physician.	Abdominal distention or diaphragmatic elevation may cause respiratory distress.
Assess for headache, muscle cramps, mental confusion, and disorientation.	Symptoms suggest hyponatremia or water intoxication.
Monitor equipment:	
Assess patency of catheter, noting difficulty in draining. Note presence of fibrin strings or plugs.	Slowing of flow rate or presence of fibrin suggests partial catheter occlusion requiring further evaluation or possible intervention.
Check tubing for kinks; note placement of bags. Anchor catheter so that adequate inflow and outflow are achieved.	Improper functioning of equipment may result in retained fluid in abdomen and insufficient clearance of toxins.
<b>Collaborative</b>	
Alter dialysate regimen, as indicated.	Changes may be needed in the glucose or sodium concentration to facilitate efficient dialysis.
Monitor blood glucose as prescribed when client is a diabetic.	Elevated glucose increases fluid retention and causes dialysate imbalance and reduced effectiveness of PD.
Monitor serum sodium.	Hypernatremia may be present, although serum levels can be low, reflecting dilutional effect of fluid volume overload.
Maintain fluid restriction, as indicated.	Fluid restrictions may have to be continued to decrease fluid volume overload. Between dialysis treatments, fluids accumulate in the body, particularly in the heart, lungs, and ankles.

#### NURSING DIAGNOSIS: risk for deficient Fluid Volume

##### Possibly Evidenced By

Loss of fluid through abnormal routes (e.g., use of hypertonic dialysate with excessive removal of fluid)

**NURSING DIAGNOSIS:** risk for deficient Fluid Volume (continued)**Desired Outcomes/Evaluation Criteria—Client Will****Systemic Toxin Clearance: Dialysis NOC**

Achieve desired alteration in fluid volume and weight with BP and electrolyte levels within acceptable range. Experience no symptoms of dehydration.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Peritoneal Dialysis Therapy NIC</b>	
<i>Independent</i>	
Maintain record of inflow and outflow volumes and individual and cumulative fluid balance.	Provides information about the status of client's loss or gain at the end of each exchange.
Adhere to schedule for draining dialysate from abdomen.	Prolonged dwell times, especially when 4.5% glucose solution is used, may cause excessive fluid loss.
Weigh when abdomen is empty, following initial 6 to 10 runs, then as indicated.	Detects rate of fluid removal by comparison with baseline body weight.
Monitor BP lying and sitting and pulse. Note level of jugular pulsation.	Decreased BP, postural hypotension, and tachycardia are early signs of hypovolemia.
Note reports of dizziness, nausea, and increasing thirst.	May indicate hypovolemia or hyperosmolar syndrome.
Inspect mucous membranes; evaluate skin turgor, peripheral pulses, and capillary refill.	Dry mucous membranes, poor skin turgor, and diminished pulses and capillary refill are indicators of dehydration and need for increased intake or changes in strength of dialysate.
<i>Collaborative</i>	
Monitor laboratory studies, as indicated, such as:	
Serum sodium and glucose levels	Hypertonic solutions may cause hypernatremia by removing more water than sodium. In addition, dextrose may be absorbed from the dialysate, thereby elevating serum glucose.
Serum potassium levels	Hypokalemia may occur and can cause cardiac dysrhythmias.

**NURSING DIAGNOSIS:** risk for physical Trauma**Possibly Evidenced By**

Invasive procedure (e.g., catheter inserted into peritoneal cavity, site near the bowel and bladder with potential for perforation during insertion or manipulation of the catheter)

**Desired Outcomes/Evaluation Criteria—Client Will****Risk Control NOC**

Experience no injury to bowel or bladder.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Peritoneal Dialysis Therapy NIC</b>	
<i>Independent</i>	
Have client empty bladder before peritoneal catheter insertion if indwelling catheter not present.	An empty bladder is more distant from insertion site and reduces likelihood of being punctured during catheter insertion.
Anchor catheter and tubing with appropriate connectors and/or tape. Emphasize importance of client avoiding pulling or pushing on catheter.	Reduces risk of trauma by manipulation of the catheter.
Note presence of fecal material in dialysate effluent or strong urge to defecate, accompanied by severe, watery diarrhea.	Suggests bowel perforation with mixing of dialysate and bowel contents. This requires immediate medical intervention as it is a potentially lethal complication including peritonitis, sepsis, and death.

(continues on page 638)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Note reports of intense urge to void or large urine output following initiation of dialysis run. Test urine for sugar, as indicated.	Suggests bladder perforation with dialysate leaking into bladder. Presence of glucose-containing dialysate in the bladder will elevate glucose level of urine.
Stop dialysis if there is evidence of bowel or bladder perforation, leaving peritoneal catheter in place.	Prompt action will prevent further injury. Immediate surgical repair may be required. Leaving catheter in place facilitates diagnosing and locating the perforation.

## NURSING DIAGNOSIS: acute Pain

### May Be Related To

Physical agents (e.g., insertion of catheter through abdominal wall, catheter irritation, improper catheter placement; abdominal distention)  
 Chemical agents (e.g., infusion of cold or acidic dialysate, rapid infusion of dialysate)  
 Biological agents (e.g., infection within the peritoneal cavity)

### Possibly Evidenced By

Verbalization/coded reports of pain  
 Self-focusing  
 Guarding behaviors, positioning to avoid pain  
 Expressive behavior (e.g., restlessness, irritability)

### Desired Outcomes/Evaluation Criteria—Client Will

#### Pain Level NOC

Verbalize decrease of pain and discomfort.  
 Demonstrate relaxed posture and facial expression; be able to sleep and rest appropriately.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Pain Management: Acute NIC</b>	
<i>Independent</i>	
Investigate client's reports of pain; note intensity (using 0 to 10 [or similar] scale), location, and precipitating factors.	Assists in identification of source of pain and appropriate interventions.
Explain that initial discomfort usually subsides after the first few exchanges.	Information may reduce anxiety and promote relaxation during procedure.
Monitor for pain that begins during inflow and continues during equilibration phase. Slow infusion rate, as indicated.	Pain will occur if acidic dialysate causes chemical irritation of peritoneal membrane.
Note reports of abdominal discomfort that is most pronounced near the end of inflow.	Likely the result of abdominal distention from dialysate. Amount of infusion may have to be decreased initially. Note: Dialysis solution comes in 1.5-, 2-, 2.5-, or 3-liter bags for manual exchanges and 5- or 6-liter bags for automated exchanges. The dialysis dose can be increased by using a larger fill volume, but only within the limits of the person's abdominal capacity.
Prevent air from entering peritoneal cavity during infusion. Note report of pain in area of shoulder blade.	Inadvertent introduction of air into the abdomen irritates the diaphragm and results in referred pain to shoulder blade. This type of discomfort may also be reported during initiation of therapy or during infusions and usually is related to stretching or irritation of the diaphragm with abdominal distention. Smaller exchange volumes may be required until client adjusts.
Elevate head of bed at intervals. Turn client from side to side. Provide back care and tissue massage.	Position changes and gentle massage may relieve abdominal and general muscle discomfort.
Warm dialysate to body temperature before infusing.	Warming the solution increases the rate of urea removal by dilating peritoneal vessels. Cold dialysate causes vasoconstriction, which can cause discomfort and excessively lower the core body temperature, precipitating cardiac dysrhythmias.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Monitor for severe or continuous abdominal pain and temperature elevation, especially after dialysis has been discontinued.	May indicate developing peritonitis. (Refer to ND: risk for Infection, following.)
Encourage use of relaxation techniques, such as deep-breathing exercises, guided imagery, and visualization. Provide diversional activities.	Redirects attention and promotes sense of control.
<b>Collaborative</b> Administer analgesics, as indicated.	Relieves pain and discomfort.

### NURSING DIAGNOSIS: risk for Infection

#### Possibly Evidenced By

Alteration in skin integrity (skin contaminants at catheter insertion site, contamination of the catheter during insertion  
Invasive procedure—periodic changing of tubing and bags; sterile peritonitis [response to the composition of dialysate])

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Risk Control NOC

Identify interventions to prevent or reduce risk of infection.

##### Infection Severity NOC

Experience no signs or symptoms of infection.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Infection Protection NIC</b> <i>Independent</i> Observe meticulous aseptic technique and wear masks during catheter insertion, dressing changes, and whenever the system is opened. Change tubing per protocol.	Prevents the introduction of organisms and airborne contamination that may cause infection, the most common complication of PD. Infection can be associated with problems at the exit or skin tunnel sites or multiple disconnections of the transfer tubings during dialysis procedures, as well as impaired immune system functioning.
Change dressings as indicated, being careful not to dislodge the catheter. Note character, color, odor, or drainage (if any) from insertion site.	Moist environment promotes bacterial growth. Purulent drainage at insertion site suggests presence of local infection, often involving skin organisms, which can be difficult to treat and sometimes require catheter removal and temporary HD. Note: Polyurethane adhesive film (e.g., blister film) dressings have been found to decrease amount of pressure on catheter and exit site as well as reduce the incidence of site infections.
Observe color and clarity of effluent fluid.	Cloudy effluent is suggestive of peritoneal infection.
Cleanse the insertion site with antibiotic solutions such as povidone-iodine (Betadine) or chlorhexidine (CHG, Hibiclens™) per protocol.	Helps reduce infective agents on the skin.
Cleanse the distal, clamped portion of catheter prior to reattachment, when intermittent dialysis therapy used.	Reduces risk of bacterial entry through catheter between dialysis treatments when catheter is disconnected from closed system.
Investigate reports of nausea or vomiting, increased or severe abdominal pain, rebound tenderness, or fever.	Signs and symptoms suggesting peritonitis, requiring prompt intervention.
<b>Collaborative</b> Monitor white blood cell (WBC) count of effluent.	Presence of WBCs initially may reflect normal response to a foreign substance; however, continued or new elevation of WBCs suggests developing infection.

(continues on page 640)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Obtain specimens of blood, effluent, and drainage from insertion site, as indicated, for culture and sensitivity.	Identifies types of organism(s) present and influences choice of interventions. Note: Elevated leukocytes and a positive dialysate effluent culture (along with abdominal pain) are indicative of peritonitis.
Monitor the peritoneal equilibration test (PET), as indicated.	Measures the effectiveness of dialysis and points to changes in dialysis prescription that might be needed, especially in the early phase of therapy. In the clearance test, samples of used solution (drained over a 24-hour period) are collected, and a blood sample is obtained during the same day when the solution is collected. The amount of urea in the solution is compared with the amount in the blood to see how effective the current PD schedule is in clearing the blood of urea.
Administer broad-spectrum antibiotics (e.g., cephalosporins, vancomycin) intravenously or in dialysate, as indicated.	Early and vigorous antibiotic therapy may be used to treat peritonitis without having to remove PD catheter or changing to hemodialysis modality. Note: Studies are inconclusive about the advantage of one route of antibiotic administration over another. However, intraperitoneal antibiotics may be preferred over intravenous, as infection is most often localized and bacteremia is rare (Ballinger et al, 2014).

### NURSING DIAGNOSIS: risk for ineffective Breathing Pattern

#### Possibly Evidenced By

Body position that inhibits lung expansion [abdominal pressure, restricted diaphragmatic excursion, rapid infusion of dialysate]

Pain

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Respiratory Status: Ventilation NOC

Display an effective respiratory pattern with clear breath sounds and arterial blood gases (ABGs) within client's normal range.

Experience no signs of dyspnea or cyanosis.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Respiratory Monitoring NIC</b>	
<i>Independent</i>	
Monitor respiratory rate and effort.	Tachypnea, dyspnea, shortness of breath, and shallow breathing during dialysis suggest diaphragmatic pressure from distended peritoneal cavity or may indicate developing complications.
Auscultate lungs, noting decreased, absent, or adventitious breath sounds, such as crackles, wheezes, and rhonchi.	Decreased areas of ventilation suggest presence of atelectasis, whereas adventitious sounds may suggest fluid overload, retained secretions, or infection.
Note character, amount, and color of secretions.	Client is susceptible to pulmonary infections, possibly due to chronic debilitating disease and altered immune response. Note: Death rates from pulmonary infections are estimated to be 14- to 16-fold higher in dialysis patients than in the general population (Guo et al, 2008).
Elevate head of bed or have client sit up in chair. Promote deep-breathing exercises and coughing.	Facilitates chest expansion and ventilation and mobilization of secretions.
<i>Collaborative</i>	
Review ABGs, pulse oximetry, and serial chest x-rays.	Changes in PaO <sub>2</sub> and PaCO <sub>2</sub> and appearance of infiltrates and congestion on chest x-ray suggest developing pulmonary problems.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Administer supplemental oxygen, as indicated.	Maximizes oxygen for vascular uptake, thus preventing or lessening hypoxia.
Administer analgesics, as indicated.	Alleviates pain and promotes comfortable breathing and maximal cough effort.

## HEMODIALYSIS (HD)

### I. Procedure

- a. Removal of urea and other toxic products from the bloodstream and correction of fluid and electrolyte imbalances
- b. Blood is shunted through an artificial kidney or membrane (dialyzer) for removal of toxins and excess fluid and then returned to the venous circulation.
- c. Requires placement of vascular access (Sofocleous et al., 2015)
  - i. Arteriovenous (AV) fistula: A direct connection is created surgically between a native artery and vein (termed *native arteriovenous fistulas* [AVFs]). Once matured, the fistula allows access to blood flow for dialysis through a percutaneous needlestick. Usually requires a maturation time of at least 4 to 6 weeks to heal before it can be used, which allows time for the vein to enlarge and thicken enough to withstand multiple needle sticks every week.
  - ii. AV graft (AVG): a looped tube (of polyurethane or other materials, such as bovine vessels or saphenous veins) that connects an artery to a vein; usually ready for use within 2 to 4 weeks
  - iii. Temporary access: provides immediate access with insertion of a central line catheter into a vein in the neck, chest, or groin. Used for immediate access while waiting for an AVF to mature or for short-term dialysis, such as with acute kidney failure.

**II. Types of hemodialysis (HD)**—Determining factors in which modality is chosen include the client's catabolic state, hemodynamic stability, and whether the primary goal is solute removal (e.g., uremia, hyperkalemia), fluid removal, or both (Golper, 2016).

- a. Intermittent HD
  - i. Requires permanent AV access, such as primary AV fistula or synthetic graft
  - ii. Standard modality in hemodynamically stable client with acute kidney failure (AKF)
  - iii. Permanent renal replacement therapy for client with stage 5 chronic kidney disease (CKD) who is not a candidate for kidney transplant or to whom a kidney transplant is unavailable
  - iv. Usually performed three times per week for 3 to 5 hours per procedure, or six to seven times per week for 1.5 to 2 hours
- b. Continuous renal replacement therapy (CRRT)
  - i. Blood is usually accessed via a central venous catheter.
  - ii. Treatment for acute kidney injury (AKI) with fluid and toxins removed at a continuous and slower rate than intermittent HD

- iii. Also indicated for clients with AKI who are too hemodynamically unstable to tolerate conventional hemodialysis
- iv. Commonly used types of CRRT
  - 1. Continuous arteriovenous hemofiltration (CAVH): removes fluid and solutes by convection; solute removal generally slow since no diffusion occurs
  - 2. Continuous venovenous hemofiltration (CVVH): similar to CAVH, except the venovenous access requires use of blood pump
  - 3. Slow continuous ultrafiltration (SCUF): a dehydrating procedure with no intent to substantially remove solute
  - 4. Continuous arteriovenous hemodialysis (CAVD): similar to CAVH with two exceptions—dialysate is run at low flow rate countercurrent to blood flow, and the ultrafiltration rate does not protect against the development of hypotension
  - 5. Continuous venovenous hemodialysis (CVVD): similar to CAVD but uses venous access and a blood pump
  - 6. Continuous arteriovenous hemodiafiltration (CAVHDF): similar to CAVD, except that ultrafiltration is allowed, and solute removal is aggressive. Volume of ultrafiltered fluid is large, so that replacement fluid must be given.
  - 7. Continuous venovenous hemodiafiltration (CVVHDF): similar to CAVHDF except that venous access is utilized and blood pump is needed.

### III. Statistics

- a. Morbidity: In 2014, 87.9% of all incident cases began renal replacement therapy with hemodialysis, and 63.1% of prevalent cases were receiving hemodialysis therapy. Among hemodialysis cases, 88.0% used in-center hemodialysis, and 1.8% used home hemodialysis (USRDS, 2015a). As many as 25% of hospital admissions in the dialysis population have been attributed to vascular access problems, including fistula malfunction and thrombosis (Al-Jaishi et al., 2014).
- b. Mortality: The mortality rate for hemodialysis patients in 2014 was 169 per 1000 patient-years. The reported mortality is highest in month 2 of HD but declines thereafter; this effect is more pronounced for patients aged 65 and over.
- c. Cost: Medicare expenditures for HD in 2014 were \$26.1 billion and \$87.638 per patient per year, remaining nearly flat compared to 2013 expenditures (USRDS, 2015b).

## G L O S S A R Y

- Arteriovenous (AV) fistula:** An artery, usually in the forearm, is surgically connected to a vein.
- Arteriovenous (AV) graft:** A synthetic tube or graft is surgically implanted in the arm to connect an artery and vein.
- Continuous renal replacement therapy (CRRT):** Continuous 24-hour dialysis therapy, which provides a more normal physiological response by removing plasma water more slowly, thus compensating for the loss of

intravascular volume; particularly useful in intensive care setting.

**Thrill:** Palpable vibration or buzzing sensation caused by turbulence of high-pressure arterial blood flow entering low-pressure venous system, indicating AV shunt is patent.

**Venous access:** The point on the body where a needle or catheter is inserted to gain entry to the bloodstream. AV access is via graft, fistula, or central venous line.

\*\*\*\*This plan of care addresses the typical HD procedure usually performed three times per week and carried out in the hospital, community dialysis center, or at home.

### NURSING DIAGNOSIS: risk for Injury

#### Possibly Evidenced By

[Clotting/problem with vascular access; infection]

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Hemodialysis Access NOC

Maintain patent vascular access.

Demonstrate behaviors, lifestyle changes to reduce risk factors and protect self from injury.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Hemodialysis Therapy NIC</b> <i>Independent</i>	
<b>Clotting</b>	
Assess client's pulse and tissue color distal to shunt.	Determines general circulatory status of limb.
Monitor internal AV fistula or graft patency at frequent intervals:	Clotting (thrombosis) and fistula malfunction are the most common complications (Sofocleous et al, 2015).
Palpate for thrill.	A constant vibration should be palpable above venous exit site. If the thrill stops or even feels different, this could indicate clotting. With early intervention, many clots can be dissolved or removed.
Auscultate for a bruit.	Bruit is the sound caused by the turbulence of arterial blood entering the venous system and should be audible by stethoscope, although may be very faint. If the bruit gets higher in pitch, it could mean narrowing of the blood vessels; if it stops, clot may have formed.
Observe for a decrease in amount of delivered doses of dialysis (infusion difficulties). Note color of blood in visible tubing at access site, and watch for obvious separation of cells and serum. Document and immediately report changes to appropriate provider(s).	Signs of access problems. Change of color from uniform medium red to dark purplish red suggests sluggish blood flow and early clotting. Separation in tubing is indicative of clotting. Very dark reddish-black blood next to clear yellow fluid indicates full clot formation.
Palpate skin around shunt for warmth.	Diminished blood flow results in "coolness" of shunt.
Evaluate reports of pain, numbness, and tingling; note extremity swelling distal to access.	May indicate inadequate blood supply.
Handle tubing gently and maintain cannula alignment. Limit activity of extremity. Avoid taking blood pressure (BP) or drawing blood samples in shunt extremity. Instruct client not to sleep on side with shunt or carry packages, books, or purse on affected extremity.	Decreases risks of shunt-related complications (e.g., clotting, dislodgement, or disconnection).

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<b>Infection</b>	
Assess skin around vascular access, noting redness, swelling, local warmth, exudate, and tenderness.	Signs of local infection, which can progress to sepsis if untreated.
Avoid contamination of access site. Use aseptic technique and masks when giving shunt care, applying and changing dressings, and starting and completing dialysis process.	Prevents introduction of organisms that may cause infection.
Monitor temperature. Note presence of fever, chills, and hypotension.	Signs of infection or sepsis requiring prompt medical intervention.
<b>Collaborative</b>	
Culture the site and obtain blood samples, as indicated.	Determines presence of pathogens and how best to treat.
Monitor prothrombin time (PT) and activated partial thromboplastin time (aPTT), as appropriate.	Provides information about coagulation status, identifies treatment needs, and evaluates effectiveness.
Administer medications, as indicated, for example:	
Low-dose heparin	Infused on arterial side of filter to prevent clotting in the filter without systemic side effects.
Antibiotics—systemic and topical	Prompt treatment of infection may save access and prevent sepsis.
Prepare for/assist with procedures, such as angioplasty and vascular stenting/stent grafting, or catheter-directed thrombolysis.	All three types of vascular access—AV fistula, AV graft, and venous catheter—can have complications that require further treatment or surgery. The most common complications are access infection and low blood flow due to blood clotting in the access. In the past two decades, radiological interventions have greatly improved the treatment of venous stenosis and fistula thrombosis without surgery. However, shunt revision can require surgical intervention and replacement of stenotic area or placement of new vascular access (RadiologyInfo.org, 2017; Sofocleous et al, 2015).

### NURSING DIAGNOSIS: risk for deficient Fluid Volume

#### Possibly Evidenced By

Active fluid volume loss (e.g., ultrafiltration, systemic heparinization, actual blood loss—disconnection of the shunt)  
Fluid restrictions

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Fluid Balance NOC

Maintain fluid balance as evidenced by stable vital signs, good skin turgor, moist mucous membranes, absence of bleeding, and appropriate weight.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Fluid Monitoring NIC</b>	
<i>Independent</i>	
Measure all sources of intake and output (I&O).	Aids in evaluating fluid status, especially when compared with weight. Note: Voided urine output is an inaccurate evaluation of renal function in dialysis clients. Some individuals have water output with little renal clearance of toxins, whereas others have oliguria or anuria.
Weigh daily, as well as before and after dialysis run.	Weight loss over precisely measured time is a measure of ultrafiltration and fluid removal. Dry weight determines how much excess fluid has been removed and serves as a guide for subsequent dialysis run time and solution.
Monitor BP, pulse, and hemodynamic pressures, if available, during dialysis.	Hypotension, tachycardia, and falling hemodynamic pressures suggest volume depletion.

(continues on page 644)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Observe for access site bleeding, noting severity. Elevate arm and apply firm (nonocclusive) pressure as indicated. Document and report bleeding that fails to stop or becomes hemorrhage.	Bleeding may be due to a combination of factors: (1) uremic coagulopathy, (2) large needles used for fistula cannulation, and (3) heparin used in the dialysis circuit to prevent clotting. Note: In the immediate postdialysis period, medication (Protamine) may be used to reverse the effect of heparin, thus reducing risk of heavy or life-threatening bleeding (Krause, 2015).
<b>Hemodialysis Therapy NIC</b>	
Ascertain whether diuretics and antihypertensives are to be withheld.	Dialysis potentiates hypotensive effects if these drugs have been administered.
Verify continuity of shunt or access catheter.	Disconnected shunt or open access permits exsanguination.
Apply external shunt dressing. Permit no puncture of shunt.	Minimizes stress on cannula insertion site to reduce inadvertent dislodgement and bleeding from site.
<b>Hemorrhage Emergency Measures</b>	
Attach two cannula clamps to shunt dressing. Have tourniquet available. If cannulae separate, clamp the arterial cannula first, then the venous. If tubing comes out of vessel, clamp cannula that is still in place and apply and maintain direct pressure to bleeding site. Place client in a supine or Trendelenburg position, as necessary.	Prevents massive blood loss while awaiting medical assistance if cannula separates or shunt is dislodged. Maximizes venous return if hypotension occurs.
<b>Fluid Management NIC</b>	
<i>Collaborative</i>	
Monitor laboratory studies, as indicated, such as the following:	
Hemoglobin/hematocrit (Hgb/Hct)	May be reduced because of anemia, hemodilution, or actual blood loss.
Serum electrolytes and pH	Imbalances may require changes in the dialysate solution or supplemental replacement to achieve balance.
Clotting times—PT/aPTT and platelet count	Use of heparin to prevent clotting in blood lines and hemofilter alters coagulation and potentiates active bleeding.
Administer IV solutions during dialysis, as indicated, for example:	
Normal saline (NS)	Saline or dextrose solutions, electrolytes, and NaHCO <sub>3</sub> may be infused in the venous side of continuous arteriovenous hemofilter when high ultrafiltration rates are used for removal of extracellular fluid (ECF) and toxic solutes.
Volume expanders, such as albumin	Volume expanders may be required during or following hemodialysis if sudden or marked hypotension occurs.
Packed red blood cells (RBCs), if needed	Destruction of RBCs (hemolysis) by mechanical dialysis, hemorrhagic losses, or decreased RBC production may result in profound and progressive anemia requiring corrective action.
Reduce rate of ultrafiltration during dialysis, as indicated.	Reduces the amount of water being removed and may correct hypotension or hypovolemia.
Administer protamine sulfate, as appropriate.	May be needed to return clotting times to normal or if heparin rebound occurs within 16 hours after hemodialysis.

#### NURSING DIAGNOSIS: risk for excess Fluid Volume

##### Possibly Evidenced By

Excessive [or rapid] fluid intake: receiving hemodialysis (e.g., IV, blood, plasma expanders, saline given to support BP during dialysis)

**NURSING DIAGNOSIS:** risk for excess Fluid Volume (continued)**Desired Outcomes/Evaluation Criteria—Client Will****Fluid Balance NOC**

Maintain “dry weight” within client’s normal range; be free of edema; with clear breath sounds and serum sodium levels within normal limits.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Fluid Monitoring NIC</b>	
<i>Independent</i>	
Measure all sources of I&O. Weigh routinely.	Aids in evaluating fluid status, especially when compared with weight. Weight gain between treatments should not exceed 0.5 kg or approximately 1 lb/d.
Monitor BP and pulse.	Hypertension and tachycardia between hemodialysis runs may result from fluid overload and heart failure (HF).
Note rate and regularity of pulse.	Rapid rate, or irregularity in heart rate, may indicate changes in volume status.
Note presence of peripheral or sacral edema, respiratory crackles, dyspnea, orthopnea, distended neck veins.	Fluid volume excess due to inefficient dialysis or repeated hypervolemia between dialysis treatments may cause or exacerbate HF, as indicated by signs and symptoms of respiratory and systemic venous congestion.
<i>Collaborative</i>	
Monitor serum sodium levels. Restrict sodium intake, as indicated.	High sodium levels are associated with fluid overload, edema, hypertension, and cardiac complications.
Restrict fluid intake as indicated, spacing allowed fluids throughout a 24-hour period.	The intermittent nature of hemodialysis results in fluid retention and volume overload between procedures and may require fluid restriction. Spacing fluids helps reduce thirst.

**URINARY DIVERSIONS: UROSTOMY (POSTOPERATIVE CARE)****I. Procedure**

- a. Diversion of urine out of the body through an opening in the abdominal wall bypassing the bladder, which requires a pouch to be worn outside the body
- b. Types: At present, several varieties of urinary diversions are performed using different bowel segments and based on the individual’s disease, functional condition, and desire. Both continent and incontinent (also called noncontinent) urinary diversions are being performed, although the latter is still done more frequently. In recent years (and especially in larger surgical centers), client may be offered a continent cutaneous diversion or an orthotopic neobladder urinary reconstruction (ONR) (Siracusano et al, 2012).
  - i. Noncontinent urinary diversions
    - 1. Ileal conduit (or urostomy): **most common type of the procedure**
    - 2. Colonic conduit: uses a segment of the bowel to anastomose ureters to the anterior body wall for ostomy bag drainage
    - 3. Cutaneous ureterostomy: directly anastomoses ureters to anterior body wall for ostomy bag drainage
  - ii. Continent urinary diversions (Costa & Kreder, 2016)
    - 1. Uses bowel segments (either ileum or combination of ileum and ascending colon fashioned into a spherical

shape for a reconstructed bladder [pouch] that is anastomosed to the urethra). This is known as an orthotopic diversion.

- 2. Orthotopic diversions are categorized into three types:
  - i. Neobladder diversion (also known as orthotopic neobladder reconstruction [ONR]), widely accepted as a first procedure where possible (Herdiman et al, 2013)
  - ii. Continent catheterizable diversion: A one-way valve is fashioned at the insertion site that leads into the reconstructed urinary storage system. Catheterization is carried out through a small stoma on the abdominal wall.
  - iii. Ureterosigmoidostomy: consists of anastomosing the ureters to the sigmoid colon in a nonrefluxing manner. This diversion method relies on the anal sphincter for continence and is rarely performed.

- II. Indications (Costa & Kreder, 2016)—Need for urostomy is associated with several factors, which is connected to a problem in the urinary system that needs to be removed or bypassed, or disorders resulting in severe incontinence, including:

- a. Bladder cancer, primary or metastatic, requiring cystectomy—**fourth most common cancer in men in the United States** (American Cancer Society [ACS], 2017)

(continues on page 646)

- b. Neurologic dysfunction, such as may occur from a birth defect, trauma, surgery, or spinal injury, causing intractable incontinence
  - c. Severe radiation injury to the bladder
  - d. Chronic pelvic pain syndromes, such as might occur with chronic prostatitis without evidence of urinary tract infection, Crohn's disease, interstitial cystitis, past sexual abuse, pelvic inflammatory disease (Mayo Clinic Staff, 2017)
- III. Statistics (ACS, 2017; National Cancer Institute, Surveillance, Epidemiology, and End Results [SEER], 2017)**
- a. Morbidity: In 2013, a nationwide inpatient sample study of trends in urinary diversion reported that 92% of patients

undergoing radical cystectomy for bladder cancer received incontinent urinary diversion, while 8% patients received continent diversion in the time period from 2001 to 2008 (Kim et al, 2013). In 2014, there were an estimated 696,440 people living with bladder cancer in the United States.

- b. Mortality: It is estimated by both the ACS and SEER that 16,870 deaths from bladder cancer occurred in 2017.
- c. Costs: Estimates of national expenditures for treatment of bladder cancer in 2016 were \$4.5 billion (NCI, 2017).

## G L O S S A R Y

**Appliance:** Pouch and accessories worn over stoma to collect urine.

**Colonic conduit:** Similar to an ileal conduit but uses a segment of colon instead of ileum.

**Continent urinary diversion:** Ureters carry urine to a pouch or reservoir created inside the body from a section of stomach or small or large intestine.

**Cystectomy:** Surgical removal of the urinary bladder.

**Enterostomal:** A surgically created permanent opening into the intestine through the abdominal wall.

**Ileal conduit:** Ureters are anastomosed to a segment of ileum, usually 15 to 20 cm long, and resected with the blood supply intact. The proximal section is closed, and the distal end is brought through an opening in the skin to form a stoma or a passageway, not a storage reservoir.

**Incontinent or noncontinent urinary diversions:** Urine flows through ureters directly anastomosed to the abdominal wall (cutaneous ureterostomy) or into a short segment of ileum or colon also attached to the abdominal

wall where the urine drains into an external collecting device through a permanent stoma.

**Intractable incontinence:** Loss of bladder control that becomes impossible to manage, alleviate, or remedy.

**Orthotopic neobladder:** A urinary reservoir fashioned from a bowel segment that is in the normal anatomic position of the bladder and attached directly to the urethra, with discharge of urine through the urethra.

**Peristomal:** Skin around and closest to the stoma.

**Stoma:** An opening that, when used in reference to ostomy care, is the segment of bowel or ureter brought to the surface of the abdomen. It is formed of mucosal tissue and is red and moist in appearance.

**Ureterostomy:** The ureter(s) is brought directly through the abdominal wall to form its own stoma.

**Urostomy:** Surgically constructed method of bypassing a dysfunctional or removed bladder in order to discharge urine. Most commonly, a conduit is created from a section of the ileum and the ureters are connected to it. The open end of the conduit is brought to the abdomen to create a stoma.

## CARE SETTING

Client is treated in acute surgical unit.

## RELATED CONCERNs

Cancer, general considerations, page 945

Peritonitis, page 389

Psychosocial aspects of care, page 835

Surgical intervention, page 873

## CLIENT ASSESSMENT DATABASE

Data depend on underlying problem, duration, and severity, for example, malignant bladder tumor, congenital malformations, trauma, chronic infections, or intractable incontinence due to injury or disease of other body systems, such as with multiple sclerosis. (Refer to appropriate CP.)

### DIAGNOSTIC DIVISION MAY REPORT

### MAY EXHIBIT

#### TEACHING/LEARNING

- **Discharge plan considerations:** May require assistance with management of ostomy and acquisition of supplies

► Refer to section at end of plan for postdischarge considerations.

PREOPERATIVE DIAGNOSTIC STUDIES	
TEST	WHAT IT TELLS ME
<b>URINE TESTS</b>	
• <i>Urodynamic tests (e.g., may include uroflowmetry, postvoid residual measurement, cystometric test, leak point pressure measurement, pressure flow study, electromyography, video urodynamic tests)</i>	Any or all of these tests may be done preoperatively to determine the presence of urinary tract obstruction, or urine storage abnormalities, and help determine which urinary diversion will be most appropriate (Costa & Kreder, 2016).
• <i>Blood tests (e.g., serum creatinine [CR] liver function tests [LFTs])</i>	A contraindication to any type of continent diversion is compromised renal function or chronic renal failure.
<b>OTHER DIAGNOSTIC STUDIES</b>	
• <i>Imaging studies (e.g., ultrasound, CT, MRI)</i>	Will have been done to determine the etiology for which urinary diversion is required.
• <i>Intravenous pyelogram (IVP) and retrograde pyelogram:</i> X-ray examination and fluoroscopic visualization of the kidneys, ureters, and bladder using contrast material. Retrograde pyelogram requires cystoscopy and the placement of a small tube into the lower part of the ureter to inject contrast and opacify the ureter and renal pelvis.	Study of choice for evaluating a person for a urinary diversion procedure if the client is not azotemic from kidney insufficiency or allergic to contrast media (Costa & Kreder, 2016). Shows size, shape, and location of urinary structures. Identifies filling defects caused by tumors or other obstructive disorders. Retrograde pyelogram may also be done to delineate urinary tract system anatomy in preparation for surgery.
• <i>Cystoscopy with biopsy:</i> Diagnostic procedure that uses a cystoscope (endoscope), which is specially designed to examine the bladder, lower urinary tract, and prostate gland. It can also be used to perform biopsies. Ultraviolet cystoscopy outlines bladder lesions. Bladder washings can also be done during cystoscopy for cytological evaluation.	Initially, may be done to evaluate painless hematuria. If bladder tumor is detected, biopsy will be done to stage the malignancy.
• <i>Pelvic magnetic resonance imaging (MRI) or computed tomography (CT) scans:</i> Imaging techniques that use x-rays, or magnetic energy, and computer analysis to provide a complete picture of pelvic body tissues and structures.	Defines size of tumor mass and degree of cancer spread into surrounding tissues.

**NURSING PRIORITIES**

1. Prevent complications.
2. Assist client and significant other (SO) in physical and psychosocial adjustment.
3. Support independence in self-care.
4. Provide information about procedure, prognosis, treatment needs, potential complications, and resources.

**DISCHARGE GOALS**

1. Complications prevented or minimized.
2. Adjusting to perceived or actual changes.
3. Self-care needs met by self or with assistance, as necessary.
4. Procedure, prognosis, therapeutic regimen, and potential complications understood and sources of support identified.
5. Plan in place to meet needs after discharge.

\*\*\*\*This plan of care primarily addresses the nursing care of the client with incontinent urinary diversion with a permanent stoma and urine-collecting device.

**NURSING DIAGNOSIS: risk for impaired Skin Integrity****Possibly Evidenced By**

- Excretions (e.g., continuous flow of urine, improper fitting of appliance); moisture
- Chemical injury agent (e.g., reaction to skin product or chemicals)
- Mechanical factors (e.g., surgery, removal of adhesive)

(continues on page 648)

**NURSING DIAGNOSIS:** **risk for impaired Skin Integrity** (continued)**Desired Outcomes/Evaluation Criteria—Client Will****Tissue Integrity: Skin and Mucous Membranes NOC**

Display timely healing of stoma and peristomal skin.

**Ostomy Self-Care NOC**

Identify individual risk factors.

Demonstrate behaviors and techniques to promote healing and prevent skin breakdown.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Ostomy Care NIC</b> <i>Independent</i> Be aware of skin problems common to urostomies (e.g., rashes, ill-fitting pouch openings, allergies to adhesives, urine pooling).	Helps guide assessment and points to appropriate interventions. Early identification of changes provides for timely interventions to prevent skin complications (resources for interventions and rationale in this section: American Cancer Society [ACS], 2014; Wound, Ostomy and Continence Nurses Society [WOCN], 2012).
Inspect stoma frequently in early postoperative period.	Stoma should be pink or reddish, similar to mucous membranes. Color changes may be temporary, but persistent changes could require surgical intervention.
Ensure proper opening for adhesive backing of pouch. Using a stoma-measuring guide or ostomy sizer, find the smallest opening that fits over the stoma and does not allow any skin exposure. Cut the barrier to size with adequate adhesive area left to apply pouch.	Prevents trauma to the stoma tissue and protects the peristomal skin from effects of urine pooling and crystallizing on the skin. Adequate adhesive area is important to maintain a pouch seal, but too tight a fit may cause stomal edema or stenosis.
Measure stoma periodically, for example, each appliance change for first 6 weeks, then monthly times six.	As postoperative edema resolves, size of appliance must be altered to ensure proper fit so that urine is collected as it flows from the stoma and contact with the skin is prevented.
Touch stoma gently as needed.	Important to prevent irritation. Mucosa has good blood supply and bleeds easily with rubbing or trauma. Note: Small spots of blood on (or from) the stoma are normal in early postoperative period.
Cleanse peristomal skin with water and pat dry.	Maintaining a clean and dry peristomal area helps prevent or limit severity of skin reaction. Note: Soap is not usually needed but may be used to remove oily residual from adhesive.
Apply effective sealant barrier, such as Skin Prep or similar product, as recommended by appliance manufacturer. Consider the use of extended wear barrier, when indicated.	Protects skin from pouch adhesive, enhances adhesiveness of pouch, and facilitates removal of pouch when necessary. The extended wear barrier does not break down like a standard wear barrier when it comes in contact with urine.
Use a transparent, odor-proof, drainable pouch. Keep gauze square over stoma while cleansing area, and have client cough or strain before applying skin barrier wafer.	A transparent appliance during first 4 to 6 weeks allows easy observation of stoma and ureteral stents (when used), without necessity of removing appliance and irritating skin. Covering stoma prevents urine from wetting the peristomal area during pouch changes. Coughing empties distal portion of conduit, followed by a brief pause in drainage to facilitate application of appliance.
Avoid use of karaya-type appliances.	Will not protect skin because urine melts karaya.
Connect collecting pouch to continuous bedside drainage system when necessary or desired.	May be needed during times when rate of urine formation is increased, such as while intravenous (IV) fluids are administered or at night if client prefers. Weight of the urine can cause pouch to pull loose and leak when pouch becomes more than half full.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Cleanse ostomy pouch on a routine basis, using vinegar solution or commercial product designed for this purpose.	Frequent pouch changes are irritating to the skin and should be avoided. Emptying and rinsing the pouch with vinegar or commercial solution not only removes bacteria but also deodorizes the pouch.
Change pouch every 3 to 7 days, or as needed for leakage. Remove appliance gently while supporting skin. Use adhesive removers as indicated and wash off completely.	Prevents tissue irritation or damage associated with pulling skin barrier wafer off.
Investigate reports of burning or itching around stoma.	Suggests peristomal irritation or possibly yeast infection, both requiring intervention. Note: Continuous exposure of skin to urine can cause hyperplasia around stoma, affecting pouch fit and increasing risk of infection.
Evaluate adhesive product and appliance fit on an ongoing basis.	Provides opportunity for problem-solving. Determines need for further intervention.
Monitor for distention of lower abdomen in presence of ileal conduit; assess bowel sounds.	Intestinal distention can cause tension on new suture lines with possibility of rupture.
<b>Collaborative</b> Consult with ostomy nurse specialist.	Ostomy nurse specialist can help client and caregiver by providing support and education, helping with problem-solving and choosing products appropriate for client's stoma characteristics, evaluating physical and mental status, and seeking financial resources. The client or caregiver should be capable of changing ostomy appliance prior to discharge or receive home care until such time as the client is able to provide self-care.
Apply antifungal spray or powder, as indicated.	Assists in healing if peristomal irritation is caused by fungal infection. Note: These products can have potent side effects and should be used sparingly. Creams and ointments are to be avoided because they interfere with adhesion of the appliance.

## NURSING DIAGNOSIS: disturbed Body Image

### May Be Related To

Illness; alteration in body structure/function (e.g., presence of stoma, loss of control of usual means of urine elimination)

### Possibly Evidenced By

Alteration in view of one's body (e.g., appearance, structure, function); actual change in structure and function (ostomy)

Fear of reaction by others

Negative feeling about body; avoids looking at/touching body part [stoma]

### Desired Outcomes/Evaluation Criteria—Client Will

#### Body Image NOC

Demonstrate beginning acceptance by viewing and touching stoma and participating in self-care.

Verbalize understanding of body changes; begins to express feelings about situation.

Verbalize acceptance of self in situation, incorporating change into self-concept without negating self-esteem.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Body Image Enhancement NIC</b>	
<b>Independent</b> Review reason for surgery and future expectations.	Client may find it easier to accept and deal with an ostomy done for chronic or long-term disease, such as intractable incontinence or infections, than for traumatic injury or cancer.

(continues on page 650)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Ascertain whether counseling was initiated when the possibility or necessity of urinary diversion was first discussed.	Provides information about client's and SO's levels of knowledge about individual situation and process of acceptance. Client with new ostomy is also often struggling to adjust to cancer or other devastating medical condition requiring the diversion.
Answer all questions concerning urostomy and its function.	Establishes rapport and conveys interest and concern of caregiver. Provides additional information for client to consider.
Encourage client and SO to verbalize feelings. Acknowledge normality of feelings of anger, depression, and grief over loss.	Provides opportunity to deal with issues and misconceptions. Helps client and SO to realize that feelings are not unusual and that feeling guilty for them is not helpful.
Note behaviors of withdrawal, increased dependency, manipulation, or noninvolvement in care.	Suggestive of problems in adjustment that may require further evaluation and more extensive therapy. May reflect grief response to loss of body part and function, worry over acceptance by others, and fear of further disability or loss of life from cancer.
Provide opportunities for client and SO to view and touch stoma, using the moment to point out positive signs of healing, normal appearance, and so forth.	Although integration of stoma into body image can take months or even years, looking at the stoma and hearing comments made in a normal, matter-of-fact manner can help client with this process. Touching stoma reassures client and SO that it is not fragile.
Provide opportunity for client to deal with ostomy through participation in self-care.	Independence in self-care helps improve self-esteem.
Maintain positive approach during care activities, avoiding expressions of disdain or revulsion. Do not take client's angry expressions personally.	Assists client and SO to accept body changes and feel all right about self. Anger is most often directed at the situation and lack of control individual has over what has happened.
Plan stoma care activities with client.	Promotes client's sense of control and gives message that client can handle this situation, enhancing self-esteem.
Discuss contacting a person with a urostomy and make arrangements for visit if client desires.	Having a visit from person of same gender and type of procedure can provide an empathetic and valuable support to client in early days of adjustment and self-care. Shared experiences can facilitate acceptance of change as client realizes "life does go on" and can be relatively normal.
Discuss sexual functioning and potential physical changes that may occur or medications that affect sexual function, if applicable. (Refer to ND: risk for Sexual Dysfunction.)	Client may experience anticipatory anxiety and fear of failure in relation to sex after surgery, often because of lack of knowledge. Surgery that removes both the bladder and prostate may disrupt parasympathetic nerve fibers that control erection in men. Newer techniques may be used in individual cases to preserve nerve function.

## NURSING DIAGNOSIS: acute Pain

### May Be Related To

Biological injury agent (e.g., disease process [cancer], trauma)  
Physical injury agent—surgical incisions, drains  
[Psychological factors—fear, anxiety]

### Possibly Evidenced By

Self-report of intensity and characteristics of pain, using standardized pain scale  
Guarding, protective behaviors  
Expressive behaviors—restlessness  
Self-focus  
Changes in vital signs

**NURSING DIAGNOSIS:** **acute Pain** (continued)**Desired Outcomes/Evaluation Criteria—Client Will****Pain Level NOC**

Verbalize relief or control of pain.

Appear relaxed and be able to sleep and rest appropriately.

**Pain Control NOC**

Demonstrate use of comfort measures, relaxation skills, and diversional activities.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Pain Management: Acute NIC</b>	
<i>Independent</i>	
Assess pain, noting location, characteristics, and intensity (0 to 10 [or similar] coded scale).	Helps evaluate degree of discomfort and effectiveness of analgesia or may reveal developing complications. Surgical causes for abdominal pain usually subside gradually as healing begins. Continued or increasing pain may be a sign of infection or intestinal obstruction.
Auscultate bowel sounds; note passage of flatus.	Indicates reestablishment of bowel function. Lack of return of bowel sounds and function within a reasonable timeframe may indicate presence of complication, such as peritonitis, hypokalemia, or mechanical obstruction.
Note urine flow and characteristics, and evaluate need for more intensive interventions.	Decreased flow may reflect urinary retention due to edema, or leakage into peritoneal cavity, with failure of anastomosis. Cloudy urine may be normal initially because of mucus from intestinal tract but, if it fails to clear over time, may indicate infectious process.
Encourage client to verbalize concerns. Active-listen these concerns and provide support by acceptance, remaining with client and giving appropriate information.	Reduction of anxiety and fear can promote relaxation and comfort.
Provide comfort measures, such as back rub, repositioning, and ambulating. Assure client that position change will not injure stoma.	Activity, movement, and comfort measures can reduce muscle tension, promote relaxation, and enhance coping abilities.
Encourage use of relaxation techniques, such as guided imagery, visualization, and diversional activities.	Helps client rest more effectively and refocuses attention, which may enhance coping ability, reducing pain and discomfort.
Investigate and report abdominal muscle rigidity, involuntary guarding, and rebound tenderness.	Suggestive of peritoneal inflammation, requiring prompt medical intervention.
<i>Collaborative</i>	
Administer medications as indicated, such as opioids, analgesics, and patient-controlled analgesia (PCA).	Relieves pain, enhances comfort, and promotes rest. PCA may be more beneficial than intermittent analgesia, especially following radical resection.
Maintain patency of nasogastric (NG) tube, when used.	Decompresses stomach and intestines; prevents abdominal distention when intestinal function is impaired.

**NURSING DIAGNOSIS:** **risk for Infection****Possibly Evidenced By**

Alteration in skin integrity, stasis of body fluids

Immunosuppression; chronic illness

Invasive procedure; increased exposure to pathogens [exposure to multiple healthcare workers/settings]

**Desired Outcomes/Evaluation Criteria—Client Will****Infection Severity NOC**

Achieve timely wound healing.

Be free of signs of localized postoperative or systemic infections.

(continues on page 652)

**NURSING DIAGNOSIS:** **risk for Infection** (continued)**Risk Control: Infectious Process NOC**

Verbalize understanding of individual causative or risk factors.  
Demonstrate techniques or lifestyle changes to reduce risk.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Infection Protection NIC</b>	
<i>Independent</i>	
Empty ostomy pouch when it becomes one-third to one-half full, once continuous pouch drainage is discontinued.	Reduces risk of urinary reflux and maintains integrity of appliance seal if pouch does not have an antireflux valve.
Document urine characteristics and note whether changes are associated with reports of flank pain.	Cloudy, odorous urine indicates infection, possibly pyelonephritis; however, urine normally contains mucus after a conduit procedure because of natural secretions of the intestine.
Report sudden cessation of urethral drainage (when present).	Constant drainage usually subsides within 10 days; however, abrupt cessation may indicate plugging and lead to abscess formation.
Note red rash around stoma.	Rash is most commonly caused by yeast. Urine leakage or allergy to appliance or products may also cause red, irritated, or macerated skin.
Maintain dry dressings; change dressings as indicated.	Moist dressings act as a wick to the wound and provide media for bacterial growth.
Assess skinfold areas in groin, perineum, and under arms and breasts.	Use of antibiotics and trapping of moisture in skinfold areas increases risk of <i>Candida</i> infections.
Monitor vital signs.	An elevated temperature suggests incisional infection, urinary tract infection (UTI), or respiratory complications.
Auscultate breath sounds.	Client may be at high risk for development of respiratory complications because of length of time under anesthesia. Often this client is older and may already have a compromised immune system. Also, painful abdominal incisions cause client to breathe more shallowly than normal and to limit coughing effort. Accumulation of secretions in respiratory tract predisposes to atelectasis and infections.
<i>Collaborative</i>	
Use pouch with antireflux valve, if available.	Prevents backflow of urine into stoma, reducing risk of infection.
Obtain specimens of exudates, urine, sputum, and blood, as indicated.	Identifies source of infection and most effective treatment. Infected urine may cause pyelonephritis. Note: Urine specimen must be obtained from the conduit because the pouch is considered contaminated.
Administer medications, as indicated, for example:	
Cephalosporins, such as cefoxitin (Mefoxin) and cefazolin (Ancef)	Given to treat identified infection or may be given prophylactically, especially with history of recurrent pyelonephritis.
Antifungal powder	Used to treat yeast infections around stoma.

**NURSING DIAGNOSIS:** **impaired urinary Elimination****May Be Related To**

Surgical diversion, tissue trauma, postoperative edema

**Possibly Evidenced By**

Incontinence (loss of continence)

Changes in amount, character of urine; urinary retention

**NURSING DIAGNOSIS:** **impaired urinary Elimination** (continued)**Desired Outcomes/Evaluation Criteria—Client Will****Urinary Elimination NOC**

Display continuous flow of urine, with output adequate for individual situation.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Urinary Elimination Management NIC</b>	
<i>Independent</i>	
Note presence of stents or ureteral catheters. Label “right” and “left” (or they may be color-coded), and observe urine flow through each.	Stents and ureteral catheters may be placed during surgery to facilitate healing of internal anastomoses.
Record urinary output. Investigate sudden reduction or cessation of urine flow.	Sudden decrease in urine flow may indicate obstruction or dysfunction, such as blockage by edema or mucus, or dehydration. Note: Reduced urinary output not related to hypovolemia, associated with abdominal distention, fever, and clear, watery discharge from the incision; suggests urinary fistula, also requiring prompt intervention.
Observe and record color of urine. Note hematuria or bleeding from stoma.	Urine may be slightly blood-tinged, which should clear up in 2 to 3 days. Rubbing or washing stoma may cause temporary oozing because of vascular nature of mucosal tissues. Continued bleeding, frank blood in the pouch, or oozing around the base of stoma requires medical evaluation and intervention.
Position tubing and drainage pouch so that it allows unimpeded flow of urine. Monitor and protect stents.	Blocked drainage allows pressure to build within urinary tract, risking anastomosis leakage and damage to renal parenchyma. Note: Stents are typically left in place 5 to 10 days to make sure the ureters remain patent during the first few days of healing while the anastomosis (surgical attachment) sites heal. They are not usually sutured in place and may fall out of the urostomy the first week or so, although most surgeons prefer they remain in place at least 5 days (Cowan, 2016).
Encourage increased fluids and maintain accurate intake.	Maintains hydration and good urine flow.
Monitor vital signs. Assess peripheral pulses, skin turgor, capillary refill, and oral mucosa. Weigh daily.	Indicators of fluid balance. Reflects level of hydration and effectiveness of fluid replacement therapy.
<i>Collaborative</i>	
Administer fluids, as indicated.	Assists in maintaining hydration and adequate circulating volume and urinary flow.

**NURSING DIAGNOSIS:** **risk for Sexual Dysfunction****Possibly Evidenced By**

Alteration in body structure and function  
Vulnerability (concern about response of SO)  
Misinformation or insufficient knowledge

**Desired Outcomes/Evaluation Criteria—Client Will****Sexual Functioning NOC**

Verbalize understanding of relationship of physical condition to sexual difficulties.  
Identify satisfying, acceptable sexual practices and explore alternative methods.  
Resume sexual relationship, as appropriate.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Sexual Counseling NIC</b> <i>Independent</i>	
Ascertain client and SO's sexual relationship before surgery, if possible. Identify future expectations and desires.	Mutilation and loss of control of a bodily function can affect client's view of personal sexuality. When coupled with the fear of rejection by a partner, the desired level of intimacy can be greatly impaired. Sexual needs are very basic, and client will be rehabilitated more successfully when a satisfying sexual relationship is continued or developed. Note: Even with nerve-sparing procedures, 15% to 50% of men will experience erectile dysfunction, and 30% to 40% of women will experience painful intercourse (Costa & Kreder, 2016).
Review with client and SO anatomy and physiology of sexual functioning in relation to own situation.	Understanding normal physiology helps client and SO understand the mechanisms of nerve damage and need for exploring alternative methods of satisfaction.
Reinforce information given by the physician. Encourage questions. Provide additional information as needed.	Reiteration of previously given information assists client and SO to hear and process the knowledge again, moving toward acceptance of individual limitations or restrictions and prognosis, for example, that it may take months to regain potency after a radical procedure or that a penile prosthesis may be necessary.
Discuss resumption of sexual activities, beginning slowly and progressing, such as cuddling and caressing until both partners are comfortable with body image and function changes. Include alternative methods of stimulation, as appropriate.	Knowing what to expect in progress of recovery helps client avoid performance anxiety and reduce risk of "failure." If the couple is willing to try new ideas, this can assist with adjustment and may help achieve sexual fulfillment.
Encourage dialogue between client and SO. Suggest wearing pouch cover, T-shirt, or short nightgown.	Disguising urostomy appliance may aid in reducing feelings of self-consciousness and embarrassment during sexual activity.
Encourage use of sense of humor.	Laughter can help individuals deal more effectively with difficult situation and promote a positive sexual experience.
Problem-solve alternative positions for coitus.	Minimizing awkwardness of appliance and physical discomfort can enhance satisfaction.
Discuss and role-play possible interactions or approaches when dealing with new sexual partners.	Rehearsal helps deal with actual situations when they arise, preventing self-consciousness about "different" body image.
Provide birth control information, as appropriate, and stress that impotence does not mean client is necessarily sterile.	Confusion about impotency and sterility can lead to an unwanted pregnancy.
<b>Collaborative</b>	
Arrange meeting with an ostomy visitor or support group, if appropriate.	Sharing of how these problems have been resolved by others can be helpful and reduce sense of isolation.
Refer for counseling or sex therapy, as indicated.	If problems persist longer than several months after surgery, a trained therapist may be required to facilitate communication between client and partner.

**NURSING DIAGNOSIS:** **deficient Knowledge regarding condition, prognosis, treatment, self-care, and discharge needs**

**May Be Related To**

Insufficient information or knowledge of resources; misinformation presented by others; insufficient interest in learning

**Possibly Evidenced By**

Insufficient information

Inaccurate follow-through of instruction or performance of urostomy care

Development of preventable complications

Inappropriate or exaggerated behaviors—hostile, agitated, apathetic, withdrawn

<b>NURSING DIAGNOSIS:</b>	<b>deficient Knowledge regarding condition, prognosis, treatment, self-care, and discharge needs</b> (continued)
<b>Desired Outcomes/Evaluation Criteria—Client Will</b>	
<b>Knowledge: Chronic Disease Management NOC</b> Verbalize understanding of condition, disease process, prognosis, and potential complications.	
<b>Ostomy Self-Care NOC</b> Participated in learning process. Perform necessary procedures correctly and explain reasons for the action. Initiate necessary lifestyle changes and participate in treatment regimen.	

ACTIONS/INTERVENTIONS	RATIONALE
<b>Teaching: Disease Process NIC</b> <i>Independent</i>	
Evaluate client's emotional and physical capabilities.	These factors affect client's ability to master tasks and willingness to assume responsibility for ostomy care.
Review anatomy, physiology, and implications of surgical intervention. Discuss future expectations.	Provides knowledge base from which client can make informed choices and an opportunity to clarify misconceptions regarding individual situation.
Include written and visual resources.	Provides references after discharge to support client efforts for independence in self-care.
Instruct client/SO in stomal care, as appropriate. Allow time for return demonstrations and provide positive feedback for efforts.	Promotes positive management and reduces risk of improper ostomy care and development of complications.
Discuss ways to ensure that stoma and appliance are odorless and nonleaking.	When client feels confident about urostomy, energy and attention can be focused on other tasks.
Recommend routine trimming of hair around stoma to edges of pouch adhesive.	Hair can be pulled out when the pouch is changed, causing irritation of hair follicles and increasing risk of local infection.
Encourage optimal nutrition.	Promotes wound healing and increases utilization of energy to facilitate tissue repair. Anorexia may be present for several months postoperatively, requiring conscious effort to meet nutritional needs.
Discuss use of acid-ash diet: cranberries, prunes, plums, cereals, rice, peanuts, noodles, cheese, poultry, and fish; avoidance of salt substitutes, sodium bicarbonate, and antacids; and cautious use of products containing calcium.	May be useful in acidifying urine to decrease risk of infection and crystal or stone formation. Products containing bicarbonate or calcium potentiate risk of crystal and stone formation, affecting both urinary flow and tissue integrity.
Discuss importance of maintaining normal weight.	Changes in weight can affect size of stoma and appliance fit. Note: Weight loss of 10 to 20 lb is not uncommon because of intestinal involvement and anorexia.
Stress necessity of increased fluid intake of at least 2 to 3 L/d (or as prescribed) and cranberry juice or ascorbic acid and vitamin C tablets. Explain to client that urine should be pale yellow to almost colorless.	Maintains urinary output and promotes acidic urine to reduce risk of infection and stone formation.
Discuss resumption of presurgery level of activity and possibility of sleep disturbance, anorexia, and loss of interest in usual activities.	Client should be able to manage same degree of activity as previously enjoyed and in some cases increase activity level, except for contact sports. "Homecoming depression" may occur, lasting several months after surgery, requiring patience, support, and ongoing evaluation.
Encourage regular activity and exercise program.	Immobility or inactivity increases urinary stasis and calcium shift out of bones, potentiating risk of stone formation and resultant urinary obstruction or infection.
Emphasize need for smoking cessation, if indicated. Refer for medication and smoking cessation assistance if client is cooperative.	Smoking cessation is critical to the health of the new bladder, ureters, and kidneys because of the vasoconstrictive, acidic, and carcinogenic effects of smoking.

(continues on page 656)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Identify signs and symptoms requiring medical evaluation: changes in character, amount, and flow of urine; unusual drainage from wound; fatigue or muscle weakness; anorexia; abdominal distention; and confusion.	Early detection and prompt intervention of developing problems (e.g., UTI, ureteral stricture, intestinal fistula) may prevent more serious complications. Urinary electrolytes, especially chloride, are reabsorbed in the intestinal conduit, which leads to compensatory bicarbonate loss, lowered serum pH or metabolic acidosis, and potassium deficit.
Emphasize importance of follow-up appointments.	Monitors healing and disease process and provides opportunity for discussion of appliance problems, general health, and adaptation to condition.
Identify community resources, such as the United Ostomy Association, local ostomy support group, enterostomal therapist, visiting nurse, and pharmacy or medical supply house.	Continued support after discharge is essential to facilitate the recovery process and client's independence in care. Enterostomal nurse can be very helpful in solving appliance problems and identifying alternatives to meet individual client needs.

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

**In addition to postsurgical concerns:**

- **impaired urinary Elimination**—anatomic diversion
- **situational low Self-Esteem**—loss of or altered control of body function
- **risk for ineffective Health Management**—complexity of therapeutic regimen, perceived barriers

## URINARY STONES (CALCULI)

### I. Pathophysiology (Chirag et al, 2016; Massini et al, 2014)

Urolithiasis is the presence of stones (uroliths/calculi) anywhere in the urinary tract caused by accumulation of solid material (crystals), which is damaging to the lining of the urinary tract and decreases the inhibitor substances that would prevent crystal accumulation.

- a. Stones most commonly are formed in the kidney and leave the body in the urine stream. There may be a single or multiple calculi, ranging in size from very small (a grain of salt) to the size of a pebble or larger (such as the staghorn calculus, which fills the kidney pelvis, with branches extending into the infundibula and calices).
- b. Client may remain asymptomatic until a stone moves into a ureter or urine flow is obstructed, at which time the potential for renal damage is acute and the level of pain is at its highest.
- c. Heredity may play a part in hypercalciuria; some familial correlations have been found.
- d. Risk factors: The lifetime risk of kidney stones is about 19% in men and 9% in women. In men, the first episode is most likely to occur after age 30, but it can occur earlier (NKF, 2016).

### II. Etiology

- a. Formed of mineral deposits—predominantly calcium oxalate and calcium phosphate. *Note:* About 75% to 85% of renal calculi are calcium stones. Uric acid (5% to 10%), struvite (5%), and cystine (1%) are also calculus formers.
- b. Casual associations have been made with:
  - i. Certain chronic conditions (e.g., cystic fibrosis, inflammatory bowel disease, gout; hyperparathyroidism, hypertension)
  - ii. Systemic dehydration; drinking too little water over time

- iii. Exercise (too much or too little)
- iv. Obesity; eating food with too much salt or sugar over time
- v. Weight loss surgery
- vi. Prolonged bedrest or immobility such as with spinal cord injury
- vii. Excessive intake of vitamins A and D, antacids, aspirin; side effects of some medications, such as acetazolamide (Diamox), Dilantin; certain antibiotics (e.g., ceftriaxone [Rocephin], ciprofloxacin [Cipro])
- viii. Some geographic locations—southeastern United States (Wedro, 2017).

### III. Statistics

- a. Morbidity: The prevalence of kidney stones in the United States increased from 3.8% in the late 1970s to 8.8% in the late 2000s. Each year in the United States, more than 500,000 people go to emergency rooms for kidney stone problems (NKF, 2016; National Institute of Diabetes and Digestive and Kidney Diseases [NIDDK], 2015).
- b. Mortality: Rare and related to development of acute kidney injury or comorbidities. In 2015, urolithiasis was listed as the underlying cause of death in 498 people in the United States. Of those who died, the sex, race, and age group most affected were women, Caucasians, ages 85+ (CDC, 2015).
- c. Cost: In 2009, charges for emergency department visits increased to \$5 billion (does not reflect hospitalization or treatment costs). In 1984, the annual estimated financial burden imposed by urinary calculi was \$898 million, *rising to \$5.3 billion in 2014* (Ghani et al, 2014).

**G L O S S A R Y**

**Calcium oxalate stones:** Kidney stones formed by calcium and oxalate crystals, which usually develop in acidic urine.

**Calcium phosphate stones:** Kidney stones formed by calcium and phosphate crystals, which usually develop in alkaline urine.

**Calculi:** Stones or concretions, especially in the kidney, gallbladder, or urinary bladder.

**Cystine stones:** Kidney stones made of cystine crystals.

**Extracorporeal shock wave lithotripsy (ESWL):** Procedure whereby a shock wave is transmitted through the body to target a stone, thus fragmenting it.

**Hematuria:** Blood in the urine.

**Hypercalciuria:** High calcium in the urine—an inherited condition.

**Hyperoxaluria:** Excretion of excessive amounts of oxalate in the urine.

**Lithotripsy:** Procedure that uses **shock waves** to break up stones in the kidney, bladder, or ureter.

**MET:** Medical expulsive therapy; use of medications to shorten the duration of stone passage and increases the likelihood of stone passage. Medications include alpha blockers and calcium channel blockers in combination with NSAIDs.

**Pyuria:** Pus in the urine.

**Renal calyces:** The perimeter of the renal pelvis is interrupted by cuplike projections called calyces. A minor calyx surrounds the renal papillae of each pyramid and collects urine from that pyramid. Several minor calyces converge to form a major calyx. From the major calyces, the urine flows into the renal pelvis and from there into the ureter.

**Renal colic:** Flank (side) pain caused by obstruction to the flow of urine caused by kidney or ureteral stones.

**Renal pelvis:** The area at the center of the kidney where urine collects and is funneled into the ureter.

**Renal tubular acidosis:** Condition associated with dehydration, metabolic acidosis, low potassium, and high chloride. Often associated with renal stones due to hypercalciuria (high calcium in urine).

**Staghorn calculi:** Develops in the center of the kidney or pelvis, filling the entire pelvis and extending out into the calyces.

**Stent:** Tube inserted into the ureter to bypass a stone or to keep the ureter open so urine flows freely from the kidney to the bladder.

**Struvite stone:** Also known as magnesium ammonium phosphate—stones that are often present with infection.

**Ureteroscopy:** Examination of the upper urinary tract, performed with a flexible ureteroscope passed through the urethra and the bladder, and then directly into the ureter. The procedure is useful in the diagnosis and treatment of kidney stones. Smaller stones in the lower ureter can be removed in one piece, while bigger ones are usually broken before removal.

**Ureterovesical junction:** Joining of the ureters and bladder: a narrow point where stones can get lodged.

**Uric acid stones:** Kidney stones made of pure uric acid crystals. These stones develop in acidic urine.

**Urolithiasis:** A term that refers to the presence of stones in the urinary tract, while nephrolithiasis (nephro= kidney + lithiasis=stone) refers to kidney stones, and ureterolithiasis refers to stones lodged in the ureter (Wedro, 2017).

**CARE SETTING**

Treatment is often handled at the community level or as an outpatient; acute episodes occasionally require inpatient treatment on a medical or surgical unit. On occasion, surgery is necessary to remove the stone(s).

**RELATED CONCERNs**

Acute kidney injury (acute renal failure), page 595  
 Fluid and electrolyte imbalances (see *DavisPlus*)  
 Metabolic acidosis—primary base bicarbonate deficiency (see *DavisPlus*)  
 Metabolic alkalosis—primary base bicarbonate excess (see *DavisPlus*)  
 Psychosocial aspects of care, page 835

**CLIENT ASSESSMENT DATABASE**

Dependent on size, location, and etiology of calculi.

**DIAGNOSTIC DIVISION  
MAY REPORT****ACTIVITY/REST**

- Sedentary occupation or occupation in which client is exposed to high environmental temperatures

**MAY EXHIBIT**

(continues on page 658)

## CLIENT ASSESSMENT DATABASE (contd.)

### MAY REPORT (continued)

- Activity restrictions or immobility due to a preexisting condition—debilitating disease, spinal cord injury—causing bones to release more calcium

### CIRCULATION

### ELIMINATION

- Decreased urinary output, bladder fullness
- Burning, urgency with urination
- History of recent or chronic urinary tract infection (UTI)
- Previous kidney stones
- Diarrhea

### FOOD/FLUID

- Nausea and vomiting (common)
- A high-protein, high-sodium, low-calcium diet, which may increase risk of some types of stones
- Insufficient fluid intake, does not drink fluids well (common)

### PAIN/DISCOMFORT

- Acute episode of excruciating, colicky pain, with location depending on stone location; in the flank in the region of the costovertebral angle, may radiate to back, abdomen, and down to the groin and genitalia; constant dull pain suggests calculi located in the renal pelvis or calyces
- May be described as acute, severe, and not relieved by positioning or any other measures

### SAFETY

- Use of alcohol can contribute to dehydration and to uric acid stone formation.
- Fever (uncommon)

### TEACHING/LEARNING

- Family history of kidney stones, kidney disease, hypertension, gout, chronic UTI, or hereditary disease, such as renal tubular acidosis, cystinuria, hyperoxaluria
- History of small bowel disease, previous abdominal surgery, hyperparathyroidism
- Use of antibiotics, antihypertensives, sodium bicarbonate, allopurinol, phosphates, thiazides, excessive intake of calcium or vitamin D
- Use of herbal remedies for kidney stones, such as valerian, skullcap, wild yam, khella, marshmallow, slippery elm

### DISCHARGE PLAN CONSIDERATIONS

- May require dietary modifications, exercise program, pain management plan

► Refer to section at end of plan for postdischarge considerations.

### MAY EXHIBIT (continued)

- Elevated blood pressure (BP) and pulse associated with pain, anxiety, or kidney failure
- Warm, flushed skin, pallor

- Alterations in voiding pattern
- Oliguria (retention, scant urine), hematuria, pyuria

- Abdominal distention, decreased or absent bowel sounds

- Guarding, distraction behaviors, self-focusing
- Tenderness in renal areas on palpation

**DIAGNOSTIC STUDIES****TEST  
WHY IT IS DONE****WHAT IT TELLS ME****BLOOD TESTS**

- **Serum and urine blood urea nitrogen/creatinine (BUN/Cr):** Helpful in delineating obstructive uropathy due to urolithiasis.
- **Serum and urine pH**
- **Complete blood count (CBC):** Battery of screening tests, which typically includes hemoglobin (Hb); hematocrit (Hct); RBC count, morphology; and white blood cell (WBC) count and differential.
- **Blood chemistry:** Measures levels of calcium, phosphate, uric acid, sodium, potassium, chloride, bicarbonate, and albumin. If serum calcium levels are elevated, then testing for hyperparathyroidism is performed.

Blockage of urine flow below the kidneys causes postrenal azotemia (ratio greater than 15:1) without intrinsic renal disease. Abnormal levels—high in serum and low in urine—are secondary to high obstructive stones with reduced urine output.

May provide insight regarding patient's renal function and type of calculus (e.g., calcium oxalate, uric acid, cystine), respectively.

Hgb/Hct—abnormal if client is severely dehydrated or client is anemic (hemorrhage, kidney dysfunction or failure). RBCs—usually normal. WBCs—may be increased, indicating infection.

These tests are done if complications associated with kidney stones are suspected or present.

**URINE TESTS**

- **Urinalysis:** Simple screening test may suggest type of stone and presence of infection.
- **Urine (24-hour):** Measures urine volume, pH, and levels of calcium, sodium, uric acid, oxalate, citrate, and creatinine.
- **Urine culture:** Identifies presence of infection and causative agent.

Color may be yellow, dark brown, or bloody. Commonly shows RBCs, WBCs, crystals (cystine, uric acid, calcium oxalate), casts, minerals, bacteria, and pus. The pH may be less than 5.0, which promotes cystine and uric acid stones, or higher than 7.5, which promotes magnesium, struvite, phosphate, or calcium phosphate stones.

Helps identify degree of obstruction and type of stone—especially important for long-term management in client who is prone to stone formation.

May reveal UTI and identify organism (e.g., *Staphylococcus aureus*, *Proteus*, *Klebsiella*, *Pseudomonas*) as cause for stone development—struvite or infection stone.

**OTHER DIAGNOSTIC STUDIES**

- **Unenhanced renal computed tomography [helical (spiral CT scan):** Continuous motion image providing detailed views of the kidneys, ureters, and bladder in a shorter period of time.
- **Abdominal x-ray of kidneys-ureters-bladder (KUB):** Usually ordered to evaluate hematuria flank pain.
- **Kidney ultrasound and intrarenal Doppler ultrasound:** Determines obstructive changes and location of stone without the risk of kidney failure that can be induced by contrast medium.
- **Intravenous urogram (IVU; also known as intravenous pyelogram [IVP]):** Kidney x-ray performed by injecting radiopaque contrast into a vein. Multiple pictures of the kidneys are taken to follow the uptake and excretion of the contrast by the kidneys.

Identifies and delineates calculi and other masses, as well as kidney, ureteral, and bladder distention. Contrast is not used because it masks the stones. Note: This test has largely replaced IVP as the definitive diagnostic test for stones (Chirag et al, 2016).

Assess the total stone burden, as well as anatomic changes in the area of the kidneys or along the course of the ureter. May show small stones that can pass unnoticed.

Ultrasound is used to determine presence of a renal stone, and enlargement of the kidney (hydronephrosis) or ureteral dilation to the kidney. However, small kidney stones that are not obstructing may be missed. Renal Doppler ultrasound improves the detection of early obstruction by evaluating for elevated resistive index (RI) in kidney with nondilated collecting system.

Provides rapid confirmation of urolithiasis as a cause of abdominal or flank pain. Shows abnormalities in anatomical structures, such as distended ureter, and outline of calculi.

## NURSING PRIORITIES

1. Alleviate pain.
2. Maintain adequate renal functioning.
3. Prevent complications.
4. Provide information about disease process, prognosis, and treatment needs.

## DISCHARGE GOALS

1. Pain relieved or controlled.
2. Fluid and electrolyte balance maintained.
3. Complications prevented or minimized.
4. Disease process, prognosis, and therapeutic regimen understood.
5. Plan in place to meet needs after discharge.

### NURSING DIAGNOSIS: acute Pain

#### May Be Related To

Biological injury agents (e.g., tissue trauma, ureteral contractions, edema formation, cellular ischemia)

#### Possibly Evidenced By

Self-report of intensity and characteristics of pain using a standardized pain scale  
Expressive behaviors (e.g., restlessness, moaning)  
Self-focus; facial mask of pain (e.g., grimacing)  
Guarding behaviors

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Pain Level NOC

Report pain is relieved, with spasms controlled.  
Appear relaxed and able to sleep/rest appropriately.

### ACTIONS/INTERVENTIONS

### RATIONALE

#### Pain Management: Acute NIC

##### Independent

Document location, duration, intensity (0 to 10 or similar coded scale), and radiation. Note nonverbal signs—elevated BP, pulse and respirations, moaning and thrashing about.

Helps evaluate site of obstruction and progress of calculi movement. Flank pain suggests that stones are in the kidney area, upper ureter. Flank pain radiates to back, abdomen, groin, and genitalia because of proximity of nerve plexus and blood vessels supplying these areas. Sudden, severe pain may precipitate apprehension, restlessness, and severe anxiety.

Explain cause of pain and importance of notifying care providers of changes in pain occurrence or characteristics.

Provides opportunity for timely administration of analgesia and alerts care providers to possibility of passing of stone or developing complications. Sudden cessation of pain usually indicates stone passage.

Provide such comfort measures as back rub and restful environment.

Promotes relaxation, reduces muscle tension, and enhances coping.

Increase fluid intake to at least 3 to 4 L/d within cardiac tolerance.

Vigorous hydration promotes passing of stone, prevents urinary stasis, and aids in prevention of further stone formation.

Apply warm compresses to back.

Reduces muscle tension and may reduce reflex spasms.

Assist with and encourage use of focused breathing, guided imagery, and diversional activities.

Redirects attention and aids in muscle relaxation.

Note reports of increased or persistent abdominal pain.

Complete obstruction of ureter can cause perforation and extravasation of urine into perirenal space. This represents an acuter surgical emergency.

##### Collaborative

Administer medications, as indicated, for example:

Analgesics, including narcotics (e.g., morphine sulfate [Astramorph], butorphanol [Stadol]; combination opioids such as oxycodone and acetaminophen [Percocet]; and NSAIDs such as ketorolac [Toradol], diclofenac [Voltaren], and ibuprofen)

Acute renal colic may be the most painful event a person can endure. Striking without warning, the pain is often described as excruciating, and the client is unable to find a position of comfort. Parenteral narcotics are typically prescribed for acute renal colic and are often required.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Antispasmodics, such as flavoxate (Urispas) and oxybutynin (Ditropan); calcium channel blockers, such as nifedipine (Adalat); and alpha-adrenergic blockers, such as tamsulosin (Flomax)	in the early phases of treatment, but NSAIDs are also effective for moderate to severe pain. Note: Opioid and NSAIDs in combination are often more effective than either alone (Chirag et al, 2016).
Maintain patency of catheters when used.	Decreases reflex spasm and relaxes ureteral smooth muscle, which facilitates stone passage. Note: Oral analgesics, NSAIDs, and alpha-adrenergic blockers help facilitate stone passage after acute attack.
	Prevents urinary stasis or retention, reduces risk of increased renal pressure and infection.

### NURSING DIAGNOSIS: impaired urinary Elimination

#### May Be Related To

Anatomic obstruction

#### Possibly Evidenced By

Dysuria

Urgency; frequency

Retention

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Urinary Elimination NOC

Void in normal amounts of greater than or equal to 30 mL/hr and usual pattern.

Experience no signs of retention.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Urinary Elimination Enhancement NIC</b>	
<i>Independent</i>	
Note urine output and characteristics of urine.	Provides information about kidney function and presence of complications (such as infection and dehydration). Bleeding may also indicate increased obstruction or irritation of ureter.
Determine client's normal voiding pattern and note variations.	Calculi may cause urinary tract nerve excitability, which causes sensations of urgent need to void. Frequency and urgency usually increase as calculus nears the ureterovesical junction.
Encourage increased fluid intake to 3 to 4 L/d (if nausea is not present and not contraindicated by cardiac/other disease conditions).	Increased hydration dilutes urine and flushes bacteria, blood, and debris and may facilitate stone passage—especially small stones.
Strain all urine. Document any stones expelled and send to laboratory for analysis.	Retrieval of calculi allows identification of type of stone and influences choice of therapy.
Investigate reports of bladder fullness; palpate for suprapubic distention. Note decreased urine output and presence of periorbital or dependent edema.	Urinary retention may develop, causing bladder, ureteral, and kidney distention, exacerbating pain and potentiating risk of infection and renal failure.
Observe for changes in mental status, behavior, or level of consciousness (LOC).	Accumulation of uremic wastes and electrolyte imbalances can be toxic to the central nervous system (CNS).
<i>Collaborative</i>	
Maintain patency of indwelling catheters—ureteral, urethral, or nephrostomy—when used.	May be required to facilitate urine flow, preventing retention and corresponding complications. Catheters are positioned above the stone to promote urethral dilation and stone passage. Continuous or intermittent irrigation can be carried out to flush kidneys and ureters and adjust pH of urine to permit dissolution of stone fragments following lithotripsy.

(continues on page 662)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Administer medications, as indicated, for example:	
Acetazolamide (Diamox) and allopurinol (Zyloprim)	Increases urine pH (alkalinity) to reduce formation of uric acid stones. Antigout agents such as allopurinol also lower uric acid production and potential of uric acid stone formation.
Alpha-adrenergic blockers, for example: tamsulosin (Flomax), terazosin (Hytrin)	Although these drugs are designed specifically for prostatic hypertrophy, they have off-label use in treatment of kidney stones as smooth muscle relaxants, which facilitate passage of ureteral stones.
Corticosteroids, such as prednisone (Deltasone)	May be used short term to reduce tissue edema to facilitate movement of stones.
Penicillamine (Cuprimine), tiopronin (Thiola), and potassium citrate (Polycitra-K)	Drugs may be prescribed to make urine more alkaline or bind cystine in the urine when cystine stones cannot be controlled.
Ammonium chloride and potassium or sodium phosphate	Reduces phosphate stone formation.
Antibiotics	Antibiotics may be needed in presence of UTI or to keep urine bacteria-free to prevent struvite stone formation.
Monitor laboratory studies, for example:	
Electrolytes, BUN, and Cr	Elevated BUN, Cr, and certain electrolytes indicate presence and degree of kidney dysfunction.
Urine culture and sensitivities	Determines presence of UTI, which may be causing or complicating kidney stone symptoms; determines appropriate antibiotic therapy.
Prepare client for and assist with endoscopic procedures, such as the following:	For treatment of most kidney stones, shock wave lithotripsy, ureteroscopy, and percutaneous nephrolithotomy have largely replaced open surgery. Note: Extracorporeal shock wave lithotripsy (SWL) and ureteroscopy (URS) with endoscopic lithotripsy are both accepted first-line therapies, according to the American Urology Association guidelines on the management of ureteric calculi (Grasso et al, 2016).
Therapeutic ureteroscopy	Performed with a flexible scope passed through the urethra and the bladder and then directly into the ureter. The most common indication for therapeutic ureteroscopy is to treat upper urinary tract stones, particularly those that are either unsuitable for extracorporeal shock wave lithotripsy (EWSL) or unresponsive to that form of treatment. Smaller stones in the lower ureter can be removed in one piece, while bigger ones are usually broken before removal. A basket procedure is sometimes performed through the scope to retrieve a stone once located in the ureter. Stents are sometimes placed after ureteroscopy, to help prevent ureteric obstruction and pain resulting from ureteral edema or passage of a stone fragment (Grasso et al, 2016; Preminger, 2016).
Shock wave lithotripsy (SWL), also called extracorporeal shock wave lithotripsy (ESWL)	SWL is the most frequently used outpatient procedure for treatment of smaller stones in the upper ureters that are not responsive to medical therapies and is effective 60% of the time (NKF, 2009; Preminger, 2016). Stones are pulverized by shock waves delivered from outside the body while client reclines in water bath or on soft cushion. Note: ESWL is not ideal for large stones.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Percutaneous nephrolithotomy (PNL) or open incision stone removal	PNL and open surgery are equally effective for the management of renal stones. PNL is a minimally invasive procedure to remove stones from the kidney by means of a small puncture wound through the skin. It is most suitable to remove stones of more than 2 cm in size and that are present near the kidney pelvic region. It is usually done under general anesthesia or spinal anesthesia. Open surgery may be necessary in less than 1% (Preminger, 2016) to remove a stone that is (1) too large to pass through ureters (e.g., >8 mm in diameter), (2) is caught in a difficult place, (3) blocks flow of urine, (4) causes or exacerbates ongoing urinary tract infection (UTI), (5) causes constant bleeding, or (6) is potentially damaging to kidney tissue. One advantage to the open procedure is that stone fragments are removed at surgery rather than relying on natural passage from the kidneys or urinary tract. Client may have a small drainage tube left in kidney or ureters during the healing process.

NURSING DIAGNOSIS:	risk for deficient Fluid Volume
<b>Possibly Evidenced By</b>	
Active fluid volume loss (e.g., nausea, vomiting) Failure of regulatory mechanisms (e.g., postobstructive diuresis)	
<b>Desired Outcomes/Evaluation Criteria—Client Will</b>	
<b>Fluid Volume NOC</b>	Maintain adequate fluid balance as evidenced by vital signs and weight within client's normal range, palpable peripheral pulses, moist mucous membranes, and good skin turgor.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Fluid/Electrolyte Management NIC</b>	
<i>Independent</i>	
Monitor and document I&O, noting 24-hour fluid balance.	Comparing actual and anticipated output may aid in evaluating presence and degree of renal impairment. Note: Impaired kidney functioning and decreased urinary output can actually result in higher circulating volumes with signs and symptoms of heart failure (HF).
Document incidence and note characteristics and frequency of vomiting and diarrhea, as well as accompanying or precipitating events.	Nausea or vomiting and diarrhea are commonly associated with renal colic because celiac ganglion serves both kidneys and stomach. Documentation may help rule out other abdominal occurrences as a cause for pain or pinpoint calculi.
Increase fluid intake to 3 to 4 L/d within cardiac tolerance.	Maintains fluid balance for homeostasis and “washing” action that may flush the stone(s) out. Note: Patients with recurrent kidney stones traditionally have been instructed to drink enough fluid to decrease chance of urinary supersaturation with stone-forming salts. The goal is a total urine volume in 24 hours in excess of 2 liters (Chirag et al, 2016).
Monitor vital signs. Evaluate pulses, capillary refill, skin turgor, and mucous membranes.	Indicators of hydration and circulating volume and need for intervention.
Weigh daily.	Rapid weight changes suggest water loss or retention.
<i>Collaborative</i>	
Monitor Hgb/Hct and electrolytes.	Assesses hydration and effectiveness of, or need for, interventions.

(continues on page 664)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Administer IV fluids.	Maintains circulating volume if oral intake is insufficient, promoting renal function.
Provide appropriate diet, clear liquids, and bland foods, as tolerated.	Easily digested foods decrease gastrointestinal (GI) activity or irritation and help improve fluid and nutritional balance.
Administer medications, as indicated, for example, anti-emetics, such as metoclopramide (Reglan), ondansetron (Zofran), promethazine (Phenergan), or droperidol (Inapsine).	Reduces nausea and vomiting.

**NURSING DIAGNOSIS:** **deficient Knowledge regarding condition, prognosis, treatment, self-care, and discharge needs**

**May Be Related To**

Insufficient information or interest in learning  
Insufficient knowledge of resources

**Possibly Evidenced By**

Insufficient knowledge  
Inaccurate follow-through of instructions or performance of a procedure

**Desired Outcomes/Evaluation Criteria—Client Will**

**Knowledge: Acute Illness Management NOC**

Verbalize understanding of disease process and potential complications.  
Correlate symptoms with causative factors.  
Verbalize understanding of therapeutic needs.  
Initiate necessary lifestyle changes and participate in treatment regimen.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Teaching: Disease Process NIC</b>	
<b>Independent</b>	
Review disease process and future expectations.	Provides knowledge base from which client can make informed choices.
Emphasize importance of increased fluid intake (including water, coffee, milk), roughly 3 to 4 L/d if not contraindicated. Encourage client to notice dry mouth and excessive diuresis or diaphoresis and to increase fluid intake whether or not feeling thirsty.	Water is essential for stone formers as it significantly reduces calcium oxalate and calcium phosphate saturation, and uric acid production. Water also flushes renal system, decreasing opportunity for urinary stasis and stone formation. Research has shown that other fluids taken in sufficient volume (such as coffee [diuretic effect] and milk [raises urinary volume, meets calcium dietary reference intake (DRI), and chelates oxalate in foods and beverages]) are also beneficial in reducing stone formation (Goldfarb et al, 2005). Increased fluid losses or dehydration require additional intake beyond usual daily needs.
Review dietary regimen, as individually appropriate, for example:	Diet may or may not be an issue. However, understanding reason for modifications provides opportunity for client to make informed choices, increases cooperation with regimen, and may prevent recurrence.
Avoid excess salt and protein. Advise that client discuss with physician or nutritionist specific recommendations for protein and animal fat.	If a person is susceptible to forming stones, then foods high in animal proteins and salt may increase the risk; however, if a person isn't susceptible to forming stones, diet probably will not change that risk. There is lack of consensus among clinicians concerning how little or how much protein affects stone formation, because studies have not produced sufficient evidence one way or another. Some clinicians have concluded that eating amounts of protein near the DRI does not increase risk of

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Low-oxalate diet, such as limited chocolate, beets, nuts, rhubarb, strawberries, spinach, and wheat bran	stone formation or recurrence, even if protein is from animal sources. Others are concerned that consuming meat increases renal acid load and may cause supersaturation of calcium, phosphate, and uric acid (Massini et al, 2014).
Avoid very high (>2500 mg/d) or very low (<500 mg/d) total intake of calcium and aim for the dietary reference intake (DRI) of 800 to 1000 mg/d. Use calcium citrate when supplements are required.	Reduces calcium-oxalate stone formation. Note: Research suggests that daily inclusion of coffee, beer, or wine decreases the risk of stone formation, whereas regular intake of apple or grapefruit juice increases the risk (Finkelstein & Goldfarb, 2006; Massini et al, 2014).
Shorr regimen: low-calcium and phosphorus diet with aluminum carbonate gel 30 to 40 mL 30 minutes after meals and at bedtime.	Research suggests that restricting dietary calcium is not helpful in reducing calcium stone formation and may actually increase oxalate stone formation (Ross et al, 2011). Use of citrate (such as in Diet 7Up, Sprite Zero, diet ginger ale) is protective against kidney stones by binding oxalate and improving calcium utilization (Eisner et al, 2010).
Encourage foods rich in magnesium and vitamins B and K.	Prevents phosphoric calculi by forming an insoluble precipitate in the GI tract, reducing the load to the kidney nephrons. Also effective against other forms of calcium calculi. Note: May cause constipation.
Discuss medication and herbal supplement regimen, avoidance of over-the-counter (OTC) drugs, and reading all product and food ingredient labels.	These nutrients reduce stone formation.
Encourage client to reveal all medications and herbs to physician or pharmacist.	Drugs may be given to acidify or alkalinize urine, depending on underlying cause of stone formation. Ingestion of products containing individually contraindicated ingredients, such as calcium and phosphorus, potentiates recurrence of stones. Note: Some herbal supplements—valerian, skullcap, wild yam, khella, and marshmallow—are known to have antispasmodic properties or are soothing to irritated urinary tissues.
Emphasize need for smoking cessation, when indicated.	To reduce risk of dangerous interactions and side effects.
Encourage regular activity and exercise program.	Cigarette smoking may contribute to kidney stones because it increases urine levels of cadmium, a heavy metal.
Active-listen to concerns about therapeutic regimen and lifestyle changes.	Inactivity contributes to stone formation through calcium shifts and urinary stasis.
Identify signs and symptoms requiring medical evaluation, such as recurrent pain, hematuria, and oliguria.	Helps client work through feelings and gain a sense of control over what is happening.
Demonstrate proper care of incisions or catheters if present.	With increased probability of stone recurrence, prompt interventions may prevent serious complications, including heightened risk of end-stage renal disease. Rate of recurrence at 1 year is 14%; at 2 years, 35%; and at 10 years, 52% (Chirag et al, 2016). Note: A recent study reported that in recurrent stone formers, there is elevated risk for both chronic kidney disease and all-cause mortality, most likely the result of repeated, transient reductions in kidney function that accompany each episode of kidney stone formation (Haley et al, 2016).
	Promotes competent self-care and independence.

**POTENTIAL CONSIDERATIONS** following acute hospitalizations (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

- **impaired urinary Elimination**—recurrence of calculi

# Women's Health

## HYSTERECTOMY

### I. Indications—surgical removal of female reproductive organ(s)

- a. Malignancies: Hysterectomy may be used to treat uterine, cervical, and ovarian cancers. Cancer of the uterus, or endometrial cancer, is the most common gynecological cancer in the United States, accounting for approximately 10% of hysterectomies (West, 2009).
- b. Nonmalignant conditions, such as endometriosis, fibroid tumors, pelvic support problems (e.g., uterine prolapse), chronic pelvic pain, abnormal uterine bleeding. *Note:* The most common reason for hysterectomy is uterine fibroids (American College of Obstetrics and Gynecologists [ACOG], 2015).
- c. Life-threatening bleeding or hemorrhaging, such as obstetric or traumatic complication; irreparable rupture of the uterus
- d. Treatment of intractable pelvic infection

### II. Hysterectomy Types and Approaches

- a. Hysterectomy is classified according to (1) how much of the reproductive organs are removed, (2) surgical approach, and (3) which reproductive organs are removed.
- b. Types
  - i. Partial (subtotal): Only the upper portion of the uterus is removed, leaving the cervix intact. Other reproductive structures may or may not be removed.
  - ii. Total: Surgical removal of the entire uterus and the cervix and in some cases, one or both ovaries (oophorectomy). When a total hysterectomy also involves the removal of ovaries and fallopian tubes, it is known as salpingo-oophorectomy hysterectomy.
  - iii. Radical: Removes the entire uterus and often the ovaries, fallopian tubes, and lymph nodes in the pelvis and/or abdomen for cancerous cells or tumors.
- c. Approaches
  - i. Laparoscopic: an innovative, minimally invasive procedure that can be performed as a vaginal or abdominal procedure
  - ii. Robotic hysterectomy: uses a computer to control the surgical instruments during surgery, which often includes the use of laparoscopic technology. A procedure known as daVinci™ hysterectomy is currently the most commonly used form of robotic hysterectomy (Hysterectomy.com staff, 2017).
  - iii. Abdominal hysterectomy
    1. This is the most common type of hysterectomy.

2. Cancer of the ovary(s) and uterus, endometriosis, and large uterine fibroids is treated with a total abdominal hysterectomy (TAH).
3. May be subtotal (partial) or total. A TAH typically requires a 4- to 6-week recovery period.
4. When an open abdominal approach is used, the incision may be horizontal or vertical, depending on the reason the procedure is performed and the size of the area being treated.
5. Procedure may also be performed via laparoscopically assisted abdominal supracervical hysterectomy (LASH), which spares the cervix, and can usually be done on outpatient basis, with a recovery period of about 1 week.

#### iv. Vaginal hysterectomy

1. Limited to certain conditions, such as uterine prolapse, cystocele or rectocele, carcinoma in situ, and high-risk obesity
2. Requires removal of cervix
3. Advantages: less pain, no visible (or much smaller) scar, shorter hospital stay, and shorter recovery period
4. May be laparoscopically assisted hysterectomy (LAVH)

### III. Statistics

- a. Morbidity: In 2010, it was reported that 500,000 hysterectomies were performed annually (ACOG, 2011). Research supports that early stage uterine cancer has the potential to be cured with surgery alone. The LAP2 trial study of 1696 women reported that open and laparoscopic approaches were equivalent in terms of overall survival (McNally & Berek, 2011).
- b. Mortality: A study published in 2013 reported that the overall mortality rates in a group of 664,229 women at 741 U.S. hospitals who had abdominal hysterectomies between 1998 and 2010 was 0.17% (Wright et al, 2013).
- c. Cost: Direct care costs have been variously reported between \$3.7 and \$5 billion for both abdominal and vaginal hysterectomies (2009 data) (Gor, 2015; Pfunter et al, 2012). A study published in 2012 (based on 2009 data) comparing costs for different types of hysterectomy reported mean total patient costs of \$43,622 for abdominal, \$31,934 for vaginal, \$38,312 for laparoscopic, and \$49,526 for robotic hysterectomies (Wright et al, 2012).

## G L O S S A R Y

**Cervix:** Lower end or neck of the uterus, which protrudes into the vagina.

**DUB:** Dysfunctional uterine bleeding (a common symptom in women undergoing hysterectomy when bleeding does not respond to other treatments).

**Endometriosis:** Ectopic endometrial tissue found outside the uterine cavity, usually in the ovaries, fallopian tubes, and other pelvic structures. Endometriosis is the cause for about one-third of hysterectomies (Gor, 2015); however, there are a variety of surgical treatments that a woman can undergo to treat endometriosis depending on the severity, stage, and abundance of the endometrioma lesions (e.g., endometriosis deep excision surgery) to remove all inflammatory tissue and to help restore fertility (Sekin, 2016).

**Fibroids (also called leiomyomas or myomas):** Benign tumors that form inside or outside the uterus wall. There are five different types of fibroids, and they are identified by their location. For example, intramural fibroids located in the thick wall of the uterus (myometrium) are the most common type of fibroids and also the easiest to remove. Fibroids are the cause for about 33% of hysterectomies (Gor, 2015; Sekin, 2015).

**Laparoscopy:** Use of a slender, light-transmitting tube to view abdominal organs or perform surgery.

**Menopause:** Permanent cessation of menstrual activity.

**Uterine prolapse:** Displacement or sagging of the uterus into the vagina. Prolapse accounts for about 15% of hysterectomies (Gor, 2015).

## CARE SETTING

Procedure is performed in inpatient acute surgical unit or short-stay unit or outpatient, depending on type performed.

## RELATED CONCERNS

Cancer, general considerations, page 945

Psychosocial aspects of care, page 835

Surgical intervention, page 873

Venous thromboembolism (VTE) disease including deep vein thrombosis (DVT) and pulmonary embolism (PE), page 120

## CLIENT ASSESSMENT DATABASE

Data depend on the underlying disease process and the need for surgical intervention—cancer, prolapse, dysfunctional uterine bleeding, severe endometriosis, or pelvic infections unresponsive to medical management—and associated complications, such as anemia.

## TEACHING/LEARNING

### DISCHARGE PLAN CONSIDERATIONS

- May need temporary help with transportation and homemaker and maintenance tasks

► Refer to section at end of plan for postdischarge considerations.

## PREOP DIAGNOSTIC STUDIES

### WHY IT IS DONE

- **Pelvic examination:** Identifies uterine and/or other pelvic organ irregularities.
- **Pap smear:** Screening test for cervical cancer and certain vaginal or uterine infections.
- **Pelvic ultrasound or computed tomography (CT) scan:** Creates an electronic picture of the organs and structures within the pelvis.
- **Sonohysterogram:** A saline-enhanced sonogram or ultrasound.

### WHAT IT TELLS ME

- |  |
|--|
| May reveal masses, tender nodules, visual changes of cervix, requiring further diagnostic evaluation.                                    |
| Cellular dysplasia reflects possibility of or actual presence of cancer, which may affect choice of procedure.                           |
| Aids in identifying size and location of pelvic mass.  |
| Evaluates abnormal growths inside the uterus, lining of the uterus, and deeper tissue layers. Delineates polyps and submucosal fibroids. |

(continues on page 668)

## PREOP DIAGNOSTIC STUDIES (contd.)

WHY IT IS DONE (continued)	WHAT IT TELLS ME (continued)
<ul style="list-style-type: none"> <li>• <b>Hysteroscopy:</b> Uses fiberoptic viewing scope and a distending medium, such as carbon dioxide, to directly view the uterine cavity and/or biopsy growths.</li> <li>• <b>Laparoscopy:</b> Visualizes pathology, obtains biopsies, or performs laser treatment for endometriosis.</li> </ul>	Viewed by some to be the “gold standard.” Determines cause of abnormal bleeding.
<ul style="list-style-type: none"> <li>• <b>Endometrial sampling:</b> Dilation and curettage (D&amp;C) with biopsy of endometrial or cervical tissue for histopathological study of cells.</li> <li>• <b>Schiller's test (staining of cervix with iodine):</b> Useful in identifying abnormal cells.</li> <li>• <b>Complete blood count (CBC):</b> Useful in determining general health status.</li> </ul>	<p>May reveal source of bleeding, presence of tumors, and superficial peritoneal implants of endometriosis; determines cancer staging and assesses effects of chemotherapy.</p> <p>Determines presence and location of cancer.</p>
<ul style="list-style-type: none"> <li>• <b>Sexually transmitted disease (STD) screen:</b> Determines presence of infection, such as (human papillomavirus [HPV]).</li> </ul>	<p>Cervix turns dark brown in noncancerous areas and white or yellow in possible cancerous areas.</p> <p>Decreased hemoglobin (Hgb) may reflect chronic anemia, decreased hematocrit (Hct) suggests active blood loss, and elevated white blood cell (WBC) count may indicate inflammation and infectious process.</p> <p>Oncogenic (tumor-inducing) human papillomaviruses (HPVs) have a causal role in nearly all cervical cancers. HPV types 16 and 18 are responsible for 70% of cervical cancers (Centers for Disease Control and Prevention [CDC], 2015).</p>

### NURSING PRIORITIES

1. Prevent complications.
2. Support adaptation to change.
3. Provide information about procedure, prognosis, and treatment needs.

\*\*\*In addition to these NDs, see nursing actions and interventions listed in CP: Surgical Intervention.

NURSING DIAGNOSIS:	risk for [acute] urinary Retention
<b>Possibly Evidenced By</b>	Blockage of urinary tract (e.g., surgical trauma, surgical manipulation, effects of anesthesia; tissue edema; hematoma) [Preexisting voiding dysfunction; pain] [Sensory and motor impairment—nerve injury such as might occur after radical hysterectomy]
<b>Desired Outcomes/Evaluation Criteria—Client Will</b>	
<b>Urinary Elimination NOC</b>	Void in sufficient amounts with no palpable bladder distention. Experience no postvoid residuals greater than 100 mL

ACTIONS/INTERVENTIONS	RATIONALE
<b>Urinary Elimination Management NIC</b> <p><i>Independent</i></p> <p>Identify client at risk for postoperative urinary retention (POUR), such as can occur with vaginal, laparoscopic, radical hysterectomies; use of regional anesthesia; long duration of surgery; pelvic organ prolapse prior to surgery.</p> <p>Note voiding pattern and monitor urinary output once surgical catheter is removed.</p>	<p>Postoperative urinary retention is a frequent consequence of pelvic surgery (estimates range from 2.5%-43%) (Geller, 2014; Mueller, 2016) typically caused by bladder (detrusor) dysfunction, urethral obstruction, or failure of pelvic floor relaxation.</p> <p>May indicate urinary retention if voiding frequently in small or insufficient amounts (less than 100 mL).</p>

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Palpate bladder. Investigate reports of discomfort, fullness, and inability to void.	Perception of bladder fullness and distention of bladder above symphysis pubis indicates urinary retention.
Provide routine voiding measures, such as privacy, normal position, running water in sink, and pouring warm water over perineum.	Promotes relaxation of perineal muscles and may facilitate voiding efforts.
Provide and/or encourage good perineal cleansing and catheter care when present.	Promotes cleanliness, reducing risk of ascending urinary tract infection (UTI).
Assess urine characteristics, noting color, clarity, and odor.	Urinary retention, vaginal drainage, and possible presence of intermittent or indwelling catheter increase risk of infection, especially if client has perineal sutures.
<b>Collaborative</b>	
Catheterize when indicated per protocol if client is unable to void or is uncomfortable.	Edema or interference with nerve supply may cause bladder atony or urinary retention requiring decompression of the bladder. Note: Indwelling urethral or suprapubic catheter may be inserted intraoperatively if complications are anticipated.
Maintain patency of indwelling catheter; keep drainage tubing free of kinks.	Promotes free drainage of urine, reducing risk of urinary stasis or retention and infection.
Check residual urine volume after voiding (called postresidual volume [PVR]) as indicated.	May not be emptying bladder completely; retention of urine increases possibility for infection and is uncomfortable, even painful. Note: Consensus exists that a PVR of 50 mL to 100 mL is normal, and PVR greater than 200 mL is abnormal (Gehrlich et al, 2007; Geller, 2014).

### NURSING DIAGNOSIS: risk for Constipation

#### Possibly Evidenced By

Abdominal muscle weakness; average daily activity is less than recommended for gender/age  
Postsurgical swelling [pain/discomfort in abdomen or perineal area]  
Decrease in gastrointestinal motility; eating habit change; insufficient fluid/fiber intake  
[Pharmacological—anesthesia; use of opiate analgesics]

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Bowel Elimination NOC

Display active bowel sounds and peristaltic activity.  
Establish/maintain usual pattern of elimination.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Bowel Management NIC</b>	
<i>Independent</i>	
Ascertain client's usual (preoperative) elimination pattern.	Provides comparative baseline and can help identify needed interventions in current situation.
Auscultate bowel sounds. Note abdominal distention and presence of nausea or vomiting.	Indicators of presence or resolution of ileus, affecting choice of interventions.
Assist with/encourage early ambulation.	Walking helps stimulate intestinal function and return of peristalsis.
Evaluate medication regimen. Discuss with physician to address modifications, as indicated.	Helps identify drugs (including opiates) that cause or exacerbate constipation.
Evaluate daily fluid intake to note deficits. Encourage increased fluid intake, including fruit juices, when oral intake is resumed.	Promotes softer stool; may aid in stimulating peristalsis.
Provide sitz baths (when prescribed).	Promotes muscle relaxation and minimizes perineal discomfort.

(continues on page 670)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<b>Collaborative</b> Restrict oral intake as indicated.	Prevents nausea and vomiting until peristalsis returns in 1 to 2 days. Note: Studies show that early feeding after abdominal hysterectomy (oral intake of fluids or food within 24 hr of surgery, irrespective of bowel sounds) is safe and associated with reduced length of hospital stay (Charoenkwan et al, 2007).
Maintain nasogastric (NG) tube, if present.	May be inserted in surgery to decompress stomach, manage nausea and vomiting.
Provide oral fluids and advance to solid foods (with inclusion of fiber) as tolerated.	When peristalsis begins, food and fluid intake promote resumption of normal bowel elimination.
Administer medications, such as stool softeners, mineral oil, and laxatives, as indicated.	Promotes formation and passage of softer stool.

### NURSING DIAGNOSIS: risk for ineffective Tissue Perfusion (specify)

#### Possibly Evidenced By

Insufficient knowledge of disease [and surgical] process  
[Intraoperative pressure on pelvic or calf vessels; pelvic congestion, postoperative tissue inflammation, venous stasis]  
Coagulopathies

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Tissue Perfusion: (Specify) NOC

Demonstrate adequate perfusion, as evidenced by stable vital signs, palpable pulses, good capillary refill, usual mentation, and individually adequate urinary output.  
Be free of edema and signs of thrombus formation.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Postanesthesia Care NIC</b> <b>Independent</b> Monitor vital signs, palpate peripheral pulses and note capillary refill, assess urinary output and characteristics, and evaluate changes in mentation.	Indicators of adequacy of systemic perfusion, fluid or blood needs, and developing complications.
Inspect dressings and perineal pads, noting color, amount, and odor of drainage. Weigh pads and compare with dry weight if client is bleeding heavily.	Proximity of large blood vessels to operative site and/or potential for alteration of clotting mechanism (e.g., cancer) increases risk of postoperative hemorrhage.
Turn client and encourage frequent coughing and deep-breathing exercises.	Prevents stasis of secretions and respiratory complications.
Assist with and/or encourage use of incentive spirometer.	Promotes lung expansion and minimizes atelectasis.
<b>Embolus Prevention NIC</b> Avoid high Fowler's position and pressure under the knees or crossing of legs.	Creates vascular stasis by increasing pelvic congestion and pooling of blood in the extremities, potentiating risk of thrombus formation.
Instruct in/assist with and instruct in ankle and leg exercises and ambulate as soon as able.	Movement enhances circulation and prevents stasis complications.
Note erythema, swelling of extremity, or reports of pain in legs or sudden chest pain with dyspnea.	May be indicative of development of thrombophlebitis and pulmonary embolus.
<b>Collaborative</b> Apply sequential compression devices (SCDs): antiembolism stockings or pneumatic compression stocking and boots.	Aids in venous return; reduces stasis and risk of thrombosis.

### Postanesthesia Care NIC

Administer intravenous (IV) fluids and blood products, as indicated.

Replacement of blood losses maintains circulating volume and tissue perfusion.

**NURSING DIAGNOSIS:** **risk for Sexual Dysfunction****Possibly Evidenced By**

Alteration in body structure (e.g., shortening of vaginal canal)  
 Alteration in body function; decrease in sexual desire; alteration in sexual excitation/satisfaction  
 Change in self-interest [sense of femininity]

**Desired Outcomes/Evaluation Criteria—Client Will****Sexual Functioning NOC**

Verbalize understanding of changes in sexual anatomy or function.  
 Discuss concerns about body image, sex role, and desirability as a sexual partner with SO.  
 Identify satisfying and acceptable sexual practices and alternative ways of dealing with sexual expression.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Sexual Counseling NIC</b> <i>Independent</i> Be aware of client's type of surgery and reason for the procedure.	May help in anticipating concerns client may have and questions she may want to address at some point. Hysterectomy can diminish sexual function either directly because of the disconnection of the nerves and blood vessels that supply sexual energy or indirectly via the loss of critical hormones when or if the ovaries are removed or cease to function. Changes to bladder, bowel, and vagina position and function posthysterectomy can likewise affect sexual function and satisfaction.
Listen to comments of client and SO. Provide open environment for client to discuss concerns about sexuality.	Sexual concerns are often disguised as humor and/or offhand remarks. An open environment promotes sharing of beliefs or values about sensitive subject and identifies misconceptions or myths that may interfere with adjustment to situation.
Assess client's and SO's information regarding sexual anatomy, sexual expression and function, and effects of surgical procedure.	May have misinformation or misconceptions that can affect adjustment. Negative expectations are associated with poor overall outcome. Changes in hormone levels can affect libido and decrease suppleness of the vagina. Although a shortened vagina can eventually stretch, intercourse initially may be uncomfortable or painful.
Identify cultural or value factors and conflicts present.	May affect return to satisfying sexual relationship.
Assist client to be aware of and deal with stage of grieving.	Acknowledging normal process of grieving for actual or perceived changes may enhance coping and facilitate resolution.
Encourage client to share thoughts or concerns with partner.	Open communication can identify areas of agreement and problems and promote discussion and resolution.
Problem-solve solutions to potential problems, such as postponing sexual intercourse when fatigued, substituting alternative means of expression, using positions that avoid pressure on abdominal incision, and using vaginal lubricant or vaginal estrogen product.	Helps client understand that return to desired and satisfying sexual activity can be possible. It may be of help to the client/partner to learn that there is abundant evidence in the medical literature supporting favorable sexual outcomes from hysterectomy given time for recovery. Note: Some studies have shown that many women experience improvement in their sex lives after hysterectomy (e.g., increased sexual activity, increased frequency and intensity of orgasm, reduced abdominal pain, reduced pain with intercourse) (Bradford & Meston, 2007; Flory et al, 2006; Landa, 2013).

(continues on page 672)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Discuss expected physical sensations or discomforts and changes in response, as appropriate to the individual.	Vaginal pain may be significant following vaginal procedure, or sensory loss may occur because of surgical trauma. Research data show a trend toward more problems with lubrication, arousal, and altered genital sensation after total hysterectomy as compared to vaginal hysterectomy. Altered hormone levels and loss of sensation of rhythmic contractions of the uterus during orgasm can impair sexual satisfaction for some women (ACOG, 2015). Note: Many women experience few negative effects because fear of pregnancy is gone, and relief from symptoms often improves sexual pleasure.

**Collaborative**

Refer to counselor or sex therapist as needed.

May need additional assistance to promote a satisfactory outcome.

## NURSING DIAGNOSIS: Grieving

### May Be Related To

Loss of significant object (e.g., parts and processes of body/perceived sexual role or identity)

### Possibly Evidenced By

Alteration in activity level, sleep pattern; detachment; disorganization

Finding meaning in a loss

Guilt about feeling relieved

### Desired Outcomes/Evaluation Criteria—Client Will

#### Grief Resolution NOC

Acknowledge impact or effect of the grieving process; verbalize reality of perceived loss.

Report sense of acceptance and hope for future.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Grief Work Facilitation NIC</b> <i>Independent</i> Provide open environment in which client feels free to discuss realistic feelings and concerns without confrontation.	Therapeutic communication skills, such as active listening, silence, being available, and acceptance, provide opportunity and encouragement for the client to talk freely and deal with the perceived loss. Provides opportunity for reflection aiding resolution and acceptance.
Discuss client's perceptions of self, related to anticipated changes and her specific lifestyle.	Research supports the idea that hysterectomy is physiologically and psychologically stressful for a woman, even when she desires the procedure. The prospect of hysterectomy is said to engender more stress than other comparable surgeries. Cultural beliefs may result in delaying needed surgery, increasing risk of complications and negatively impacting recovery (Armeli, 2015). Although preoperative instruction and interaction are often performed at the community level, the postoperative care providers can convey interest and concern and make opportunities for support, teaching, and correction of misconceptions, such as loss of femininity and sexuality, weight gain, and menopausal body changes.
Determine client's perception and meaning of current and past losses. Note cultural factors and expectations.	Affects client's response and needs to be acknowledged in planning care. Perceptions and way of expressing self may be result of cultural expectations.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Assess emotional stress client is experiencing.	Being aware of what this operation means to client helps avoid inadvertent casualness or excessive concern by care providers. Note: Women who have hysterectomies are at risk for some degree of depression, associated with abrupt hormonal changes and grieving the loss of body part and function. But in women in young childbearing years, depression can also be associated with the fact of never being able to bear children (or be pregnant again), as well as the premature onset of menopause.
Encourage client to vent feelings appropriately, identifying meaning of loss.	Depending on the reason for the surgery (e.g., cancer or long-term, heavy bleeding), the client may be frightened or relieved. She may mourn the loss of ability to fulfill her reproductive role whether or not she has borne children. She may also worry about her wholeness as a woman or have heard stories about problems others have had with the procedure.
Assist family/SO to cope with client's responses.	Family may not share client's perspective and be intolerant, not recognizing needs of client.
Identify and problem-solve solutions to existing physical responses—eating, sleeping, activity levels, and sexual desire.	May need additional assistance to deal with the physical aspects of the potential for grieving.
Note withdrawn behavior, negative self-talk, and overconcern with actual or perceived changes.	May indicate difficulty in working through the grief process and need for additional interventions or support.
Discuss healthy ways of dealing with difficult situation.	Provides opportunity to look toward the future and incorporate perceived loss into lifestyle.
<b>Collaborative</b> Refer to other resources for counseling, spiritual or pastoral care, and psychotherapy, as indicated.	May need additional help to prevent development of dysfunctional grieving and help client move toward a positive future.

**NURSING DIAGNOSIS:** **deficient Knowledge regarding condition, prognosis, treatment, self-care, and discharge needs**

**May Be Related To**

Insufficient information; insufficient knowledge of resources  
Misinformation presented by others

**Possibly Evidenced By**

Insufficient knowledge  
Inaccurate follow-through of instructions; development of preventable complication

**Desired Outcomes/Evaluation Criteria—Client Will**

**Knowledge: Disease Process NOC**

Verbalize understanding of condition and potential complications.  
Identify relationship of signs and symptoms related to surgical procedure and actions to deal with them.

**Knowledge: Treatment Regimen NOC**

Verbalize understanding of therapeutic needs.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Teaching: Disease Process NIC</b> <i>Independent</i> Review effects of surgical procedure and future expectations; for example, the client needs to know that she will no longer menstruate or bear children, whether surgical menopause will occur, and whether hormonal replacement will be necessary.	Provides knowledge base from which client can make informed choices.

(continues on page 674)

**ACTIONS/INTERVENTIONS (continued)**

Discuss complexity of problems anticipated during recovery, including emotional lability and expectation of feelings of depression or sadness, excessive fatigue, sleep disturbances, and urinary problems.

Discuss resumption of activity. Encourage light activities initially, with frequent rest periods, increasing activities and exercise as tolerated. Emphasize importance of individual response in recuperation.

Identify individual restrictions, such as avoiding heavy lifting and strenuous activities (such as vacuuming, straining at stool) and prolonged sitting or driving. Avoid tub baths and douching until physician authorizes.

Encourage client to report bowel dysfunction—constipation, loss of urge to defecate, severe straining, incomplete evacuation, and digital evacuation—to healthcare providers if it occurs.

Discuss dietary modifications, medicinal bulk agents, and stimulation by suppository, as indicated.

Review recommendations of resumption of sexual intercourse. (Refer to ND: risk for Sexual Dysfunction.)

Identify dietary needs, such as high-quality protein, complex carbohydrates, and additional iron. Provide information about foods to include and avoid in managing menopausal symptoms.

Review hormone replacement therapy (HRT) and route (oral, injection, patch) when used. Clarify distinction between long-term HRT use for preventive therapy and short-term use for symptom relief.

Encourage taking prescribed drug(s) routinely, for example, with meals or at bedtime. Determine when patch should be changed, wearing time altered.

Discuss potential side effects, such as weight gain, increased skin pigmentation or acne, breast tenderness, headaches, and photosensitivity.

Recommend cessation of smoking, especially when receiving estrogen therapy.

**RATIONALE (continued)**

Physical, emotional, and social factors can have a cumulative effect, which may delay recovery, especially if hysterectomy was performed because of cancer. Providing an opportunity for problem-solving may facilitate the process. Client and SO may benefit from the knowledge that a period of emotional lability is normal and expected during recovery.

Client can expect to feel fatigued when she goes home and needs to plan a gradual resumption of activities, with return to work an individual matter. Prevents excessive fatigue; conserves energy for healing and tissue regeneration.

Strenuous activity intensifies fatigue and may delay healing. Activities that increase intra-abdominal pressure can strain surgical repairs, and prolonged sitting potentiates risk of thrombus formation. Showers are permitted, but tub baths and douching may cause vaginal or incisional infections and are a safety hazard.

Constipation is a frequent symptom after hysterectomy and may be related to undiagnosed irritable bowel syndrome, which is often present preoperatively and/or associated with the particular procedure performed—vaginal hysterectomy with posterior repair.

Postsurgical bowel dysfunction may be short term or long term and may require simple home management measures or referral for medical intervention.

When sexual activity is cleared by the physician, it is best to resume activity easily and gently, expressing sexual feelings in other ways or using alternative coital positions.

Facilitates healing and tissue regeneration, helps correct anemia when present. Note: Certain vegetables, such as broccoli, cabbage, cauliflower, brussels sprouts, and turnips, may have protective action against excessive estrogen effects. Some foods and substances to avoid or limit include rich dairy products, sugar, fried foods, caffeine, alcohol, and nicotine.

Total hysterectomy with bilateral salpingo-oophorectomy results in surgically induced menopause requiring replacement hormones. Benefits of HRT, particularly estrogen, include protection against osteoporosis and the amelioration of certain postmenopausal discomforts such as sleep disturbance, hot flashes, mood disorders, problems with memory and concentration, reduced libido, and urinary symptoms. Note: Discussion of client's particular needs and concerns may be helpful if she has not decided about HRT. As the risks of estrogen therapy have been headlined in recent years, the pros and cons of HRT may be more difficult to decipher (Todd, 2016).

Establishes routine for taking drug and reduces potential for discontinuing drug because of nausea that is often an early side effect.

Development of some side effects is expected but may require problem-solving for the client to continue the hormones, such as change in dosage, change of delivery method, and use of analgesics, sunscreen, and sunglasses.

Some studies suggest an increased risk of thrombophlebitis, myocardial infarction (MI), stroke, and pulmonary emboli associated with smoking and concurrent estrogen therapy.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Inquire if client is taking or planning to take vitamins and/or herbal supplements for menopause, such as vitamin C with bioflavonoids, calcium, magnesium, selenium, evening primrose oil, black cohosh, angelica, and wild yam.	Client may express desire to use "natural hormones" and feel confused over choices. These substances are numerous and available and have been the object of media attention. They should be reviewed in terms of expected action, potential interaction, or adverse effects, depending on client's particular situation and reason for the hysterectomy.
Review incisional care, when appropriate.	Facilitates competent self-care, promoting independence.
Emphasize importance of follow-up care.	Provides opportunity to ask questions, clear up misunderstandings, and detect developing complications. Note: Client needs to discuss with the physician her particular requirements for follow-up pelvic exams with Pap smear once surgical healing has occurred. The need and rationale for these exams depend upon the client's reason for hysterectomy—benign fibroids versus cervical neoplasm.
Identify signs and symptoms requiring medical evaluation, such as fever or chills, change in character of vaginal or wound drainage, and bright red bleeding.	Early recognition and treatment of developing complications, such as infection or hemorrhage, may prevent life-threatening situations.
Identify support group and appropriate websites, as indicated.	May desire additional information or opportunity to discuss feelings or concerns with women with similar experiences.

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition, and presence of complications, personal resources, and life responsibilities)

**In addition to surgical and cancer concerns (if appropriate):**

- **risk for Sexual Dysfunction**—altered body structure and function, changes in hormone levels, decreased libido, possible change in sexual response pattern, vaginal discomfort or pain (dyspareunia)
- **risk for situational low Self-Esteem**—alteration in body image; loss (e.g., perceived changes in femininity, effect on sexual relationship, inability to have children); functional impairment (e.g., changes in sexual response pattern, decreased libido)

## MASTECTOMY

### I. Purpose

- a. Removal of breast tissue due to presence of malignant or cancerous tumor changes
- b. Surgical procedures: dependent on tumor type, size, and location as well as clinical characteristics or staging
  - i. Breast-conserving therapy (may also be called lumpectomy or partial or segmental mastectomy): treatment option for some women with small, localized breast cancers. Some lymph nodes may be removed for sampling. Radiation may follow lumpectomy. Note: Studies have shown that women who undergo breast-conserving surgery followed by radiation have similar overall survival rates as those who undergo mastectomy (Breastcancer.org Staff, 2015; Hughes, 2004; Sabel, 2017).
  - ii. Mastectomy (Martin, 2017; Mayo Clinic Staff, 2016)
    1. Simple: removes the breast tissue, nipple, areola, and skin but not all the lymph nodes
    2. Modified radical: removes the entire breast—including the breast tissue, skin, areola, and nipple—and most of the axillary lymph nodes

3. Radical: removes all breast tissue along with the nipple, axillary lymph nodes, and chest wall muscles under the breast. Note: This procedure is rarely performed today, because modified radical mastectomy has proved to be equally as effective and less disfiguring.

4. Skin-sparing mastectomy: surgical technique in which the majority of the natural breast skin envelope is not surgically removed. This procedure may be an option for the surgical management of noninvasive breast cancer (or early stage cancers in some cases). If mastectomy is being performed for preventive purposes, a skin-sparing or nipple-sparing mastectomy can provide the best cosmetic result (Kwang & Sabel, 2017).

**II. Pathology**—Tumor growth originates in cells of the breast tissue occurring primarily in women, although men may also be affected.

- a. Types: Breast cancers are either **noninvasive** (in situ) remaining in original location or **invasive** (metastasized from original location). Invasive cancers are further classified into subtypes.

(continues on page 676)

- i. Ductal
  - 1. Occurs in the ducts that connect the lobes and the nipple
  - 2. May be *in situ* or invasive
  - 3. Invasive ductal carcinoma (IDC) represents 70% to 80% of all breast cancers (Cancer Treatment Centers of America [CTCA], 2017; Carlson et al, 2013).
- ii. Lobular
  - 1. Occurs in the lobes where milk is produced
  - 2. May be *in situ* or invasive
  - 3. Occurs in 7% to 10% of women (CTCA, 2017; Carlson et al, 2013)
- b. Subtype (rare) cancers include inflammatory breast cancer (IBC), HER2-receptor positive breast cancer, endocrine-sensitive breast cancer, male breast cancer, papillary carcinoma, and Paget's disease (CTCA, 2017).
- c. Clinical staging categories (American Cancer Society [ACS], 2017a)
  - i. Classification: noninvasive, invasive (infiltrating)
  - ii. T refers to the size and spread of tumor into nearby areas (e.g., skin or chest wall under breast).
  - iii. N refers to spread of cancer in lymph nodes and how many nodes are involved.
  - iv. M refers to metastasis to other parts of body (e.g., lungs or bones).

- v. Grade measured from 0 (carcinoma *in situ*), then I (1) to IV (4)
  - vi. Some stages further divided by letters of the alphabet (A, B, C, etc.)
- III. Statistics** (ACS, 2017a; 2017b; National Cancer Institute [NCI], Surveillance, Epidemiology, and End Results [SEER], 2017)
- a. Morbidity: In 2014, approximately 3,327,552 American women were living with breast cancer; an estimated 252,710 new cases of breast cancer were diagnosed in women in 2017 and 2470 in men (ACS, 2017b).
  - b. Mortality: In 2017, breast cancer was the second leading cause of death in women in the United States; an estimated 40,610 or 6.8% of all cancer deaths in women and about 460 men died of breast cancer in 2017 (ACS, 2017b).
  - c. Cost: The National Cancer Institute (NCI) projection for breast cancer care in 2016 was \$18.9 billion (NCI, 2017). A retrospective (2010 data) analysis of 8360 women reported that average costs *per patient* in the year after diagnosis were \$60,637 (stage 0), \$82,121 (stages I and II), \$129,387 (stage III), and \$134,682 (stage IV). Treatment costs were higher for patients whose cancer was more advanced at diagnosis, and the cost difference was largely driven by the cost of chemotherapy and noncancer treatments (Blumen et al, 2016).

## G L O S S A R Y

**Adenocarcinoma:** A carcinoma that originates in glandular tissue, or tissue responsible for the production and secretion of a substance. Breast ducts and lobules are examples of glandular tissues where adenocarcinomas may sometimes develop.

**Aromatase inhibitors (AIs):** Newer drugs sometimes used in women who have already gone through menopause to treat breast cancer or reduce cancer recurrence after surgery. Instead of blocking estrogen receptors, they stop a key enzyme (called aromatase) from changing other hormones into estrogen, taking away the fuel that estrogen receptor-positive breast cancers need to grow.

**Breast-conserving therapy:** Treatment of choice for most women with stage I or stage II breast cancer and usually followed with radiation therapy.

**Carcinoma:** Cancer that originates in epithelial tissue cells, which are present both in the skin (epidermis) and in the lining of internal organs. The most common type of cancer.

**Grade:** Determined by cellular differentiation; the lower the grade, the more it resembles normal breast tissue and the least likely it is to spread.

**Invasive breast cancer:** Breast cancer that extends into the surrounding breast tissue and may metastasize.

**In situ (noninvasive) breast cancer:** Breast cancer that is contained within a structure of the breast, such as a duct or lobe.

**Lumpectomy:** Removes only the breast lump and a rim of normal surrounding breast tissue.

**Lymph node surgery:** Removal of lymph node(s) to determine if breast cancer has spread to the lymph ducts or lymph nodes in the axilla. In tumors 2 cm or smaller in size, a *sentinel* procedure may be performed to remove only the node(s) deemed most likely to contain cancerous cells. In larger tumors, or if sentinel biopsy is positive, a traditional axillary lymph node dissection is performed.

**Metastasis:** Cancer that has spread to other parts of the body.

**Modified radical mastectomy:** Removal of entire breast and some axillary (underarm) lymph nodes.

**Partial or segmental mastectomy:** Removes more breast tissue than a lumpectomy—up to one-quarter of the breast—which is then called a quadrantectomy.

**Radical mastectomy:** All the muscle under the breast is removed; however, it is rarely used today because it is no more effective than the more limited forms of mastectomy.

**Simple or total mastectomy:** Entire breast is removed, but no lymph nodes from under the arm or muscle tissue from beneath the breast are removed.

**Skin-sparing mastectomy:** Removal of the entire breast, nipple, and areola, without removal of the breast skin for immediate or delayed breast reconstruction.

**Staging:** Method to classify progression of cancer in order to select treatment options and predict a prognosis.

## CARE SETTING

Client is treated at inpatient acute surgical unit (typically short stay).

## RELATED CONCERNs

Cancer, general considerations, page 945

Psychosocial aspects of care, page 835

Surgical intervention, page 873

**CLIENT ASSESSMENT DATABASE****DIAGNOSTIC DIVISION  
MAY REPORT****MAY EXHIBIT****CIRCULATION**

- Unilateral engorgement in affected arm as a result of lymph node involvement

**EGO INTEGRITY**

- Constant stressors in work or home life
- Stress and fear involving diagnosis, prognosis, and future expectations

**FOOD/FLUID**

- Loss of appetite, recent weight loss

**PAIN/DISCOMFORT**

- Pain may be reported in advanced metastatic disease but rarely occurs in early malignancy
- Discomfort or “funny feeling” in breast tissue occurs in some clients

**SAFETY**

- Nodular axillary masses
- Edema, erythema of involved skin

**SEXUALITY**

- Changes in breast symmetry or size, pitting or dimpling of breast skin, color changes such as erythema or temperature, unusual nipple discharge, itching, burning, retracted nipple
- Concerns about sexuality and intimacy
- History of early menarche younger than age 12, late menopause after age 50, late first pregnancy, such as after age 30

- Change in breast contour or symmetry
- Retraction of nipple, discharge from nipple

**TEACHING/LEARNING**

- Family history of genetically transmitted breast cancer. *Note:* Together, *BRCA1* and *BRCA2* mutations account for about 20% to 25% of hereditary breast cancers and about 5% to 10% of all breast cancers (ACS, 2017c; Campeau et al, 2008).
- Previous unilateral breast cancer, endometrial cancer, or ovarian cancer
- History of prolonged hormone replacement therapy, radiation, or multiple breast biopsies or procedures

**DISCHARGE PLAN CONSIDERATIONS**

- May need assistance with treatments and rehabilitation, decisions, self-care activities, and homemaker or maintenance tasks

► Refer to section at end of plan for postdischarge considerations.

## DIAGNOSTIC STUDIES

TEST WHY IT IS DONE	WHAT IT TELLS ME
<ul style="list-style-type: none"> <li>• <b>Mammography:</b> Uses x-ray to visualize internal structure of the breast.</li> </ul>	Screening imaging test capable of detecting nonpalpable cancers, macrocalcifications, or tumors in early stages of development. <i>Note:</i> Diagnostic mammography allows a possible abnormality on screening images to be examined more closely.
<ul style="list-style-type: none"> <li>• <b>Diagnostic mammography:</b> A type of mammography in which more x-ray pictures of the breast are taken from different angles.</li> </ul>	
<ul style="list-style-type: none"> <li>• <b>Digital mammography:</b> Creates computer images, rather than images on film, which can be manipulated and transmitted for further review.</li> </ul>	Complements findings of mammograms. Distinguishes fluid-filled cysts from solid tumors. <i>Note:</i> Has been found to be more effective than regular mammography for women under 50, with dense breasts, or premenopausal or in early menopause.
<ul style="list-style-type: none"> <li>• <b>Ultrasound:</b> Uses sound waves to produce images for both screening and diagnostic staging.</li> </ul>	Noninvasive imaging test that may be done after mammogram has identified an area of concern to determine if a lump is solid or is filled with fluid (a cyst).
<ul style="list-style-type: none"> <li>• <b>Magnetic resonance imaging (MRI):</b> Creates images that capture multiple cross-sectional pictures using a computer to generate detailed two- and three-dimensional images.</li> </ul>	Performed when more information is needed than a mammogram, ultrasound, or clinical breast exam can provide. Ductal cancer in situ is usually better detected with an MRI than with a mammography.
<ul style="list-style-type: none"> <li>• <b>Biopsies:</b> Removal of a sample of suspicious tissue for examination by a pathologist.</li> </ul>	Biopsy determines whether a mass is benign or malignant.
<ul style="list-style-type: none"> <li>• <b>Fine-needle aspiration biopsy:</b> A fine, hollow needle is inserted into a lump or lesion and cells are withdrawn for evaluation.</li> </ul>	This is usually performed when a fluid-filled mass is detected.
<ul style="list-style-type: none"> <li>• <b>Core-needle biopsy:</b> A hollow needle is used to take several rice- or grain-sized cores of tissue.</li> </ul>	With this type of biopsy, breast tissue can be evaluated.
<ul style="list-style-type: none"> <li>• <b>Ultrasound-guided core-needle biopsy:</b> Core-needle biopsy that uses ultrasound to produce precise images of structures within the body.</li> </ul>	May be used in place of fine-needle biopsy or surgical biopsy to verify diagnosis.
<ul style="list-style-type: none"> <li>• <b>Stereotactic biopsy:</b> A special mammography machine uses x-rays to guide biopsy equipment to the site of the imaging abnormality. A core needle is then used to obtain a large tissue sample, or a vacuum-assisted device (VAD) is used to collect multiple tissue samples during one needle insertion.</li> </ul>	A lump or calcifications deep inside the breast (as seen on mammography or ultrasound), or an abnormality too small to feel, can be biopsied using this technique.
<ul style="list-style-type: none"> <li>• <b>Surgical biopsy:</b> All or part of the suspicious tissues may be removed by surgery for cytological examination.</li> </ul>	Total removal of the tissue is called an excisional biopsy, whereas partial removal is called an incisional biopsy.
<ul style="list-style-type: none"> <li>• <b>Sentinel node biopsy:</b> Surgeon removes only one axillary lymph node (or a cluster of two or three) nearest the breast to determine presence of cancerous cells.</li> </ul>	The lymph ducts of the breast drain to one (sentinel) lymph node (or a cluster of two or three nodes) filtering fluid draining away from the breast. If cancer cells are traveling in the lymph system, the sentinel node is more likely than the others to contain them. If the first node is benign, it is likely that all other nodes are the same, thereby limiting the need to remove additional nodes and reducing the potential for lymphedema (Mayo Clinic Staff, 2017).
<ul style="list-style-type: none"> <li>• <b>Gene assays</b></li> </ul>	Genetic research is revealing that genes (in addition to <i>BRCA1</i> and <i>BRCA2</i> ) have some association with breast cancers (not listed here). For example, the Food and Drug Administration (FDA) has recently approved a diagnostic test that detects mutations in 324 genes and two genomic signatures in many solid tumor types, including breast cancer and ovarian cancer (CTCA, n.d.; Wagnine, 2017).
<ul style="list-style-type: none"> <li>• <b>Human epidermal growth factor receptor 2 (HER2) tumor test:</b> A growth-promoting protein.</li> </ul>	Cancer cells with too many copies of this gene tend to grow and spread more aggressively than do other breast cancers. Approximately 20% of women with breast cancer have HER2-positive tumors (Blahd, 2016).

WHY IT IS DONE (continued)	WHAT IT TELLS ME (continued)
<ul style="list-style-type: none"> <li>• <b>BRCA1 and BRCA2:</b> Normal genes that are associated with familial breast cancer when inherited in mutated state.</li> </ul>	<p>These tests may be performed on young women with more than one family member who has developed breast cancer at an early age. According to recent estimates, 55% to 65% of women who inherit a harmful <i>BRCA1</i> mutation and around 45% of women who inherit a harmful <i>BRCA2</i> mutation will develop breast cancer by age 70 years (Chen &amp; Parmigiani, 2007; NCI, 2015). Note: <i>BRCA2</i> (and, to a lesser extent, <i>BRCA1</i>) is also associated with male breast cancer (NCI, 2015).</p>

## NURSING PRIORITIES

1. Assist client and significant other (SO) in dealing with stress of situation and prognosis.
2. Prevent complications.
3. Establish individualized rehabilitation program.
4. Provide information about disease process, procedure, prognosis, and treatment needs.

## DISCHARGE GOALS

1. Situation being dealt with realistically.
2. Complications prevented or minimized.
3. Exercise regimen implemented.
4. Disease process, surgical procedure, prognosis, and therapeutic regimen understood.
5. Plan in place to meet needs after discharge.

## PREOPERATIVE AND POSTOPERATIVE

### NURSING DIAGNOSIS: Anxiety [specify level]

#### May Be Related To

Situational crisis; threat to current status  
Major change (e.g., change in self-concept/body image; scarring/loss of body part, change in sexual attractiveness)  
Threat of death (e.g., extent of disease, uncertainty of prognosis)

#### Possibly Evidenced By

Behavioral—worried about change in life event, restlessness  
Affective—apprehensiveness; helplessness, feeling of inadequacy; fear; self-focused  
Physiological—increase in tension  
Sympathetic—changes in vital signs

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Anxiety Level NOC

Demonstrate appropriate range of feelings regarding possibility of death or increasing hope related to prognosis.  
Acknowledge acceptance of health status.

##### Anxiety Self-Control NOC

Communicate thoughts and feelings utilizing available support systems such as family, spiritual leaders, and other resources.

Demonstrate coping behaviors that reduce anxiety.

## ACTIONS/INTERVENTIONS

## RATIONALE

### Anxiety Reduction NIC

#### Independent

Ascertain what information client has about diagnosis, expected surgical intervention, and future therapies. Note presence of denial or extreme anxiety.

Provides knowledge base for the nurse to enable reinforcement of needed information, helps identify client with high anxiety or a low capacity for information processing and need for special attention. Note: Denial may be useful as a coping method initially; however, extreme anxiety needs to be dealt with immediately.

Explain purpose and preparation for diagnostic tests or procedures. Ascertain what client understands about diagnostics that have already been performed.

Promotes clear understanding of procedures and what is happening, increases feelings of control, and lessens anxiety and fear of the unknown.

(continues on page 680)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Provide an atmosphere of concern and anticipatory guidance and privacy for client and family.	Facilitates therapeutic communication and expression of underlying unresolved issues. Privacy is needed to encourage open discussion related to feelings of anticipated loss and other concerns.
Active-listen. Encourage questions and provide time for expression of fears.	Provides opportunity to identify concerns, clarify misconceptions, and offer emotional support.
Offer relaxation techniques such as back massage, guided imagery, and use of touch, if culturally acceptable.	May help in reducing anxiety and fear.
Explore previously used effective coping mechanisms as perceived by the client.	Reinforces effective coping mechanisms can be used for coping in a new situation.
Explore spiritual support as a resource.	Provides calmness and peace in times of uncertainty.
Discuss role of rehabilitation after surgery and use of community resources.	Promotes support systems in place in the rehabilitation process as an essential component of therapy intended to meet physical, social, emotional, and vocational needs so that client can achieve the best possible level of physical and emotional functioning.

### \*\*\*POSTOPERATIVE

#### NURSING DIAGNOSIS: **impaired Tissue Integrity**

##### May Be Related To

Surgical procedure (e.g., surgical removal of skin and tissue; interruption of lymphatics)  
Impaired circulation, alteration in sensation

Excessive fluid volume (edema, changes in skin elasticity)  
Chemical irritants (e.g., drainage)

##### Possibly Evidenced By

Damaged/destroyed tissues; acute pain

##### Desired Outcomes/Evaluation Criteria—Client Will

##### Wound Healing: Primary Intention NOC

Achieve timely wound healing free of purulent drainage or erythema.

##### Knowledge: Treatment Procedures NOC

Verbalize understanding of treatment plan to promote wound healing.

Demonstrate wound care techniques that facilitate increased tissue granulation at incision site.

Demonstrate behaviors that prevent complications.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Incision Site Care NIC</b>	
<i>Independent</i>	
Assess dressings and note amount and characteristics of drainage (if any).	Use of dressings depends on the extent of surgery and the type of wound closure. Pressure dressings are usually applied initially and are reinforced, not changed. Drainage occurs because of the trauma of the procedure and manipulation of the numerous blood vessels and lymphatics in the area. Normally, surgically inserted drains should allow dressings to be dry.
Provide drain care, instructing client/family in the process, as indicated.	The Jackson-Pratt (JP) drain is most commonly used for mastectomies to maintain negative pressure in the wound and is easily managed. Simple mastectomies use one drain, whereas more complex procedures, such as those involving removal of lymph nodes, may require several drains. Drains are usually removed around the third day or when drainage ceases, possibly after client is discharged.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Monitor temperature.	Early recognition of developing infection enables rapid institution of treatment.
Maintain elevated head of bed position when client is supine or on unaffected side in immediate postoperative period.	Assists with drainage of accumulated fluids through use of gravity.
Evaluate operative side arm for edema. Note client reports of discomfort (e.g., aching, feelings of heaviness or tightness).	A small amount of swelling in the arm is normal for the first 4 to 6 weeks after breast cancer surgery. However, lymphedema can occur, especially in client who, after undergoing axillary lymphadenectomy, receives radiation therapy. Note: Within this population, 10% to 40% develop some degree of upper extremity lymphedema within the first 3 years after mastectomy (Rossy & Scheinfeld, 2017; Smith & McCaulley, 2014).
Elevate hand/arm on pillows while reclining early in postoperative period. Avoid letting arm hang down or resting on hard surface for long period.	These measures can decrease congestion in arm by directing lymph into the circulatory and lymphatic system.
Avoid measuring blood pressure (BP), injecting medications, or blood draws or inserting intravenous (IV) lines in affected arm, where possible.	Increases potential of constriction, infection, and lymphedema on affected side.
Encourage wearing of nonconstrictive clothing. Advise client to avoid wearing wristwatch or other tight jewelry on affected arm/hand.	Avoiding constriction can minimize formation of lymphedema and reduce risk of skin/tissue damage.
<b>Collaborative</b>	
Maintain integrity of elastic bandages or custom-fitted, pressure-gradient elastic sleeve, as prescribed.	Gentle continuous compression promotes venous return and decreases risk or effects of edema formation.
Refer to physical and occupational therapist and lymphedema clinic or specialist.	Various therapies may be needed over time (e.g., complete decongestive therapy, manual lymph drainage measures, compression bandaging and garments, exercise and skin care, and education for self-care) (Stout-Gergich et al, 2008).

## NURSING DIAGNOSIS: acute Pain

### May Be Related To

Physical injury agents (e.g., surgical procedure; tissue trauma, interruption of nerves, dissection of muscles)

### Possibly Evidenced By

Self-report of intensity and characteristics of pain using standardized rating scale  
Guarding and protective behaviors  
Self-focused

### Desired Outcomes/Evaluation Criteria—Client Will

#### Pain Level NOC

Express reduction in pain or discomfort.  
Appear relaxed and able to sleep or rest appropriately.

#### Pain Control NOC

Identify factors that aggravate or relieve pain.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Pain Management: Acute NIC</b>	
<b>Independent</b>	
Assess reports of pain and sensory alterations, noting location, duration, and intensity (0 to 10 [or similar] scale). Note reports of stiffness, swelling, and numbness or burning in chest, shoulder, and affected arm. Identify verbal and nonverbal cues.	Examines the degree of discomfort and verifies the need for analgesia and evaluates its effectiveness. The amount of tissue, muscle, and lymphatic system removed can affect the amount of pain experienced. The need to elevate arm, the size of dressings, and the presence of drains all affect client's ability to relax and rest or sleep effectively.

(continues on page 682)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Explain the causes of pain to the client.	Provides understanding of sensory alterations. Destruction of nerves in axillary region causes numbness in upper arm and scapular region, which may be more intolerable than surgical pain. Pain in chest wall can occur from muscle tension, be affected by extremes in heat and cold, and continue for several months.
Acknowledge the presence of phantom breast sensations.	Provides reassurance that sensations are not imaginary and that relief can be obtained.
Provide basic comfort and diversional activities. Encourage early ambulation and use of relaxation techniques, guided imagery, and Therapeutic Touch.	Promotes relaxation, refocuses attention away from the discomfort, and may enhance coping abilities.
Provide opportunities for uninterrupted sleep.	Relieves fatigue, increasing coping ability.
Splint or support chest during coughing and deep-breathing exercises.	Facilitates participation in activity without undue discomfort.
Provide appropriate pain medication on a regular schedule before pain is severe and before activities are scheduled.	Maintains comfort level and permits client to exercise arm and to ambulate without pain hindering efforts.
Provide accurate information related to patient-controlled analgesia (PCA) or opioids to reduce fear of addiction.	Reduces fear, augmenting appropriate pain relief, to enhance mobility and coping abilities.
Discuss previous successful methods of coping with pain.	Provides pain-relieving methods to employ based on past experiences.

**Collaborative**

Administer PCA (patient-controlled analgesia), opioids, or nonopioids, as indicated.

Provides relief from discomfort or pain and facilitates rest and participation in postoperative therapy.

### NURSING DIAGNOSIS: risk for situational low Self-Esteem

#### Possibly Evidenced By

Physical illness

Alteration in body image (e.g., surgical change in structure or body contour)

Behavior inconsistent with values; unrealistic self-expectations

[Fear of rejection or reaction by others]

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Self-Esteem NOC

Distinguish between self-perceptions and societal stigmas.

Identify strategies to cope with self-acceptance in present situation.

Verbalize progress toward acceptance of self.

Participate in setting realistic goals involving the postoperative therapy program.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Self-Esteem Enhancement NIC</b>	
<b>Independent</b>	
Provide active listening when surgical dressings are removed.	Provides emotional support and client safety.
Assess for grief, depression, and ineffective coping.	Common reactions that need to be recognized immediately for timely intervention, as indicated. Grief may resurface when subsequent procedures are done, such as fitting for prosthesis or reconstructive procedure if postponed.
Validate client's feelings and address any misinformation that is revealed.	Encourages client to express feelings and provides opportunity to give or reinforce information.
Encourage questions about current situation and future expectations.	Loss of the breast causes many reactions, including feeling disfigured, fear of viewing scar, and fear of partner's reaction to change in body. Loss of body part, disfigurement, and perceived loss of sexual desirability engender grieving process that needs to be supported and dealt with so that client can make plans for the future.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Identify role concerns as woman, wife, mother, career woman, and so forth.	Explores possible alteration in client's self-perception.
Provide positive reinforcement for gains and improvement and participation in self-care and treatment program.	Encourages continuation of healthy behaviors.
Review possibilities for reconstructive surgery and/or prosthetic augmentation.	If feasible, reconstruction may be performed to provide a less disfiguring or "near-normal" cosmetic result. Variations in skin flap may be done for facilitation of reconstructive procedure, which may be performed at the same time as mastectomy. The associated emotional boost may help the client through the more complex surgical recovery process and adjunctive therapies. Note: Several studies have shown an increase in breast reconstruction for mastectomy. From 2009 to 2014, the rate of breast reconstruction for mastectomy increased by 62%. Increases occurred for all age groups but disproportionately so for women aged 65 years and older (Miller et al, 2017).
Identify concerns of client and SO regarding sexual dysfunction in order to provide acceptable practices for self and SO. Encourage communication of needs and fears of both partners.	Negative responses actually reflect SO's concern about hurting client, fear of cancer or death, or inability to look at operative area.
Discuss and identify support groups, as appropriate.	Provides a place to exchange concerns and feelings with others who have had a similar experience and identifies ways SO can facilitate client's recovery.

**Collaborative**

Provide temporary soft prosthesis, if indicated.	Prosthesis of nylon and Dacron fluff may be worn in bra indefinitely or until incision heals if reconstructive surgery is not performed at the time of mastectomy. This may promote social acceptance and allow client to feel more comfortable about body image at the time of discharge.
--	--

**NURSING DIAGNOSIS:** **risk for impaired physical Mobility****Possibly Evidenced By**

Decrease in range of shoulder motion; decrease in gross motor skills  
Pain, discomfort  
Decrease in muscle mass/strength; joint stiffness; postural instability

**Desired Outcomes/Evaluation Criteria—Client Will****Motivation NOC**

Display willingness to participate in therapy.  
Demonstrate techniques that enable resumption of activities.

**Coordinated Movement NOC**

Demonstrate increased muscle strength of affected body parts.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Exercise Therapy: Muscle Control NIC</b>	
<b>Independent</b>	
Note factors affecting current situation (e.g., extent of surgery, preexisting medical condition, severity of breast cancer, age of client).	Identifies potential impairments and determines types of interventions to provide for client's safety.
Evaluate client reports of various discomforts and note presence/degree of functional issues.	The most common symptoms after the mastectomy are muscle aches, swelling, limited range of motion in the upper extremity.

(continues on page 684)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Perform passive ROM, such as flexion and extension of elbow, pronation and supination of wrist, and clenching and extending fingers, as soon as possible.	Early postoperative exercises are usually started in the first 24 hours to prevent joint stiffness that can further limit movement and mobility.
Advance exercise, as indicated, for example, active extension of arm and rotation of shoulder while lying in bed, pendulum swings, rope turning, and elevating arms to touch fingertips behind head.	Helps prevent shoulder joint stiffness and maintains muscle tone of the shoulders and arm.
Progress to hand climbing or walking fingers up wall, clasping hands behind head, and full abduction exercises as soon as client can manage.	Because this group of exercises can cause excessive tension on the incision, they are usually delayed until healing process is well established.
Encourage client to use affected arm for personal hygiene: feeding, combing hair, and washing face.	Increases circulation, minimizes edema, and maintains strength and function of the arm and hand.
Evaluate degree of exercise-related pain and changes in joint mobility. Measure upper arm and forearm if edema develops.	Monitors progression and resolution of complications. May need to postpone increasing exercises and wait until further healing occurs.
Assist with ambulation as needed, and encourage correct posture.	Client may feel unbalanced and need assistance until accustomed to change. Keeping back straight prevents shoulder from moving forward, avoiding permanent limitation in movement and posture.
Instruct client to report loss of upper body strength, inability to maintain balance, or gait disturbances.	Although not common, there is a possibility of changes in balance and movement in the postsurgery period after radical mastectomy. These may be result of the loss of a large mass of tissues with millions of peripheral receptors and irritation of the peripheral nerves. In such cases, the central nervous system receives completely different information and it may confuse motor cortex (especially in older women).

#### **Collaborative**

Administer medications, as indicated, for example:

Analgesics	Pain management before exercise may help client to participate optimally.
Refer to physical and occupational therapist or specialist as needed.	Provides an individualized exercise and rehabilitation program if client is having difficulty adjusting to physical changes or is debilitated.

#### **NURSING DIAGNOSIS:** **deficient Knowledge regarding condition, prognosis, treatment, self-care, and discharge needs**

##### **May Be Related To**

Insufficient information; lack of exposure or recall

Information misinterpretation

Insufficient knowledge of resources

##### **Possibly Evidenced By**

Insufficient knowledge

Inaccurate follow-through of instructions or performance of procedure

Development of preventable complications

##### **Desired Outcomes/Evaluation Criteria—Client Will**

###### **Knowledge: Acute Illness Care NOC**

Verbalize understanding of disease process and potential complications.

Perform necessary procedures correctly and explain reasons for actions.

Initiate necessary lifestyle changes and participate in treatment regimen.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Teaching: Disease Process NIC</b> <i>Independent</i>	
Review disease process, surgical procedure, and future expectations.	Provides knowledge base from which client can make informed choices, including participation in radiation and/or chemotherapy programs. (Refer to CP: Cancer.)
Review and have client demonstrate care of drains and wound sites.	Shorter hospital stays may result in discharge with drains in place, requiring more complex care by client and caregivers. Drains will be removed when the drainage fluid is 30 mL or less for 24 hr.
Encourage continuation of exercises, increasing program as healing progresses, for at least 1 year.	Good muscle tone enhances development of collateral lymphatic channels, reduces the tightening of scar tissue, and maintains muscle strength and function.
Emphasize necessity for well-balanced, nutritious meals, and adequate fluid intake.	Provides optimal nutrition and maintains circulating volume to enhance tissue regeneration and the healing process.
Suggest alternating schedule of frequent rest and activity periods.	Prevents or limits fatigue, promotes healing, and enhances feelings of general well-being.
Discuss potential for lymphedema in affected arm and signs to watch for (e.g., feeling of fullness or tightness, aching or pain, weakness, swollen fingers). Instruct client to report these symptoms immediately to physician.	Lymphedema may occur from weeks to years especially after radical mastectomy.
Suggest gentle massage of healed incision with emollients.	Stimulates circulation, promotes elasticity of skin, and reduces discomfort associated with phantom breast sensations.
Recommend use of sexual positions that avoid pressure on chest wall. Encourage alternative forms of sexual expression such as cuddling or touching during initial healing process and while operative area is still tender.	Promotes feelings of femininity and sense of ability to resume sexual contact.
Encourage regular self-examination of remaining breast when mastectomy is unilateral. Determine recommended schedule for mammography.	Identifies changes in breast tissue indicative of recurrent or new tumor development.
Emphasize importance of regular medical follow-up.	Other treatment may be required as adjunctive therapy, such as radiation. Client may also have immediate or delayed breast reconstruction requiring ongoing evaluation.
Identify signs and symptoms requiring medical evaluation: breast or arm red, warm, and swollen; edema and purulent wound drainage; and fever or chills.	Lymphangitis can occur as a result of infection, causing lymphedema.
Address additional concerns as indicated—ongoing therapies and expected and/or adverse side effects.	Depending on the type of cancer that required the mastectomy, the client may have ongoing cancer therapies (e.g., chemotherapy, radiotherapy), selective estrogen modulators (e.g., tamoxifen [Soltamox] and raloxifene [Evista]), or aromatase inhibitors (e.g., letrozole [Femara], anastrozole [Arimidex]) to treat cancer or prevent recurrence.

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

**In addition to surgical and cancer concerns:**

- **impaired Tissue Integrity**—altered circulation, sensation; tissue removal/destruction, radiation; drainage
- **situational low Self-Esteem**—physical illness, loss, disturbed body image (e.g., disfiguring surgical procedure, concern about sexual attractiveness)
- **Self-Care deficit (specify)**—weakness, fatigue, neuromuscular impairment, pain, muscular impairment

# CHAPTER 10

## Men's Health

### BENIGN PROSTATIC HYPERPLASIA (BPH)

#### I. Pathophysiology

- a. Overgrowth of normal, nonmalignant cells that causes progressive enlargement of the prostate gland, resulting in bladder outlet obstruction with urinary retention, leakage, and frequency (Deters et al, 2017).
- b. The enlarged gland contributes to the overall lower urinary tract symptoms (LUTS) complex via at least two routes: (1) direct bladder outlet obstruction (BOO) from enlarged tissue (static component) and (2) from increased smooth muscle tone and resistance within the enlarged gland (dynamic component) (American Urological Association [AUA], 2014).
- c. Additional complications: bladder wall trabeculation, detrusor muscle enlargement, narrowing of urethra, incontinence, and acute or chronic renal failure (Springhouse, 2005).

#### II. Classification (AUA, 2014; Deters et al, 2017)

- a. The severity of BPH can be determined with the International Prostate Symptom Score (IPSS)/American Urological Association Symptom Index (AUA-SI) plus a disease-specific quality-of-life (QOL) question.
- b. Questions and subsequent scoring focus on degree of incomplete emptying, frequency, intermittency, urgency,

weak stream, straining, nocturia, as well as impact on quality of life.

- i. Score of 0 to 7: mildly symptomatic
- ii. Score of 8 to 19: moderately symptomatic
- iii. Score of 20 to 35: severely symptomatic

#### III. Etiology

- a. Cause is unknown, although testosterone and other hormones may affect growth.
- b. Microscopically characterized as a hyperplastic process with the number of cells in the gland increasing with age.

#### IV. Statistics

- a. Morbidity: BPH is the most common disorder of the prostate gland. About half of all men between the ages of 51 and 60 have BPH. Up to 90% of men over age 80 have BPH (Urology Care Foundation, 2015). An estimated 15 million men in the United States have symptoms related to benign enlargement (Egan, 2016).
- b. Mortality: generally related to renal failure, infection, and complications of surgery.
- c. Cost: The direct cost of BPH treatment (drugs, procedures, imaging, and office visits [based on 2005 data]) was estimated to be \$4 billion annually (Saigal & Joyce, 2005; Vuichoud & Loughlin, 2015).

#### G L O S S A R Y

**Benign prostatic enlargement:** Term used when there is prostate gland enlargement and is usually a presumptive diagnosis based on the size of the prostate.

**Benign prostatic hyperplasia (BPH) [also called benign prostatic hypertrophy]:** Histologic diagnosis characterized by proliferation of the cellular elements of the prostate.

**Benign prostatic obstruction (BPO):** Term used when obstruction has been proven by pressure flow studies or is highly suspected from flow rates and if the gland is enlarged.

**Bladder outlet obstruction (BOO):** Generic term for all forms of obstruction to the bladder outlet (e.g., urethral stricture).

**Bladder wall trabeculation:** Characterized by thick wall and hypertrophied muscle bundles; typically seen in instances of longstanding obstruction.

**Dysuria:** Painful, difficult urination.

**LUTS (Lower urinary tract symptoms):** Storage and/or voiding disturbances common in aging men. LUTS may be due to structural or functional abnormalities in one or more parts of the lower urinary tract that comprises the bladder, bladder neck, prostate, distal sphincter mechanism, and urethra. Not all men with BPH have LUTS, and likewise, not all men with LUTS have BPH. Note: LUTS may also result from abnormalities of the peripheral and/or central nervous systems that provide neural control to the lower urinary tract (AUA, 2014; Deters et al, 2017).

**Prostate Health Index (phi):** Test that helps distinguish between prostate cancer and benign disease and improves the specificity of prostate cancer detection in the PSA range of 2 to 10 ng/mL (Nalley, 2017).

**Prostatitis:** Inflammation of the prostate gland.

**CARE SETTINGS**

Client is treated at the community level, with more acute care provided during outpatient procedures.

**RELATED CONCERNS**

Acute kidney injury, page 595  
Prostatectomy, page 694  
Psychosocial aspects of care, page 835

**CLIENT ASSESSMENT DATABASE****DIAGNOSTIC DIVISION  
MAY REPORT****MAY EXHIBIT****CIRCULATION**

- Elevated blood pressure (BP)

**ELIMINATION**

- Feeling need to urinate urgently, sensation of imminent loss of urine without control
- Hesitancy or straining in initiating voiding, having to stand at or sit on the toilet for some time prior to producing a urinary stream
- Decreased force or caliber of urinary stream, intermittent flow, dribbling
- Usually voiding only small amounts of urine with each episode, sensation of incomplete emptying
- Need to urinate frequently during the day or night (nocturia), resulting in interrupted sleep
- Dysuria, hematuria
- Chronic constipation, resulting from protrusion of prostate into rectum

**FOOD/FLUID**

- Anorexia, nausea, vomiting
- Recent weight loss

**PAIN/DISCOMFORT**

- Suprapubic, flank, or back pain; sharp, intense, with acute prostatitis
- Low back pain

**SAFETY**

- Fever

**SEXUALITY**

- Concerns about effects of condition or therapy on sexual abilities
- Fear of incontinence or dribbling during intimacy
- Decrease in force of ejaculatory contractions
- Enlarged, tender prostate

**TEACHING/LEARNING**

- Family history of cancer, hypertension, kidney disease
- Use of antihypertensive or antidepressant medications, over-the-counter (OTC) cold and allergy medications containing sympathomimetics, urinary antibiotics or antibacterial agents
- Use of nutrients or herbal supplements for self-treatment of BPH and urinary flow—saw palmetto, pygeum, pumpkin seed oil, or soy products

**DISCHARGE PLAN CONSIDERATIONS**

- May need assistance with management of therapy—indwelling catheter

► Refer to section at end of plan for postdischarge considerations.

## DIAGNOSTIC STUDIES

### TEST

### WHY IT IS DONE

### WHAT IT TELLS ME

#### BLOOD TESTS

- **Prostate-specific antigen (PSA):** Substance manufactured solely by prostate gland cells. An elevated reading indicates an abnormal condition of the prostate gland, either benign or malignant.

Serum PSA reflects the amount of glandular epithelium, which in turn reflects prostate size. As prostate size increases with increasing age, the PSA concentration also rises; it increases at a faster rate in elderly men. As a result, different normal reference ranges may be appropriate based upon a man's age. Anything that irritates the prostate (e.g., prostatitis, prostate biopsy, recent sexual activity) will cause the PSA to rise, at least temporarily (Schmitz, 2017). Note: Using PSA numbers for screening for prostate cancer remains controversial but is still done. Although BPH does not cause prostate cancer, men at risk for BPH are also at risk for this disease (Deters et al, 2017).

#### URINE TESTS

- **Urinalysis:** Laboratory examination of urine for red blood cells (RBCs) and WBCs or presence of infection or excessive protein.
- **Postvoid residual (PVR):** Volume of urine remaining in bladder immediately after voiding.

Yellow, dark brown, dark or bright red (bloody) in color; appearance may be cloudy, pH of 7 or greater suggests infection; and bacteria, WBCs, and RBCs may be present microscopically.

Determines the severity of urinary retention; may be done by catheterization or by transabdominal ultrasound (bladder scan).

#### OTHER DIAGNOSTIC STUDIES

- **Ultrasound (abdominal, renal):** Diagnostic imaging technique utilizing reflected high-frequency sound waves to delineate, measure, or examine internal body structures.
  - **Transrectal prostatic ultrasound (TRUS):** Examination where a fingerlike probe is placed in the rectum and ultrasound pictures are made of the prostate.
  - **Digital rectal exam (DRE):** Test performed by inserting gloved finger into rectum to detect prostate abnormalities.
  - **Uroflowmetry:** Measures urine amount and flow rate via a collection device and scale. The equipment creates a graph that shows changes in flow rate from second to second, measuring peak flow rate and how long it took to get there.
  - **Urography:** Series of x-rays of the kidney, ureters, and bladder after injection of a contrast dye into a vein.
  - **Cystourethrography:** Allows visualization of the bladder and urethra on x-ray, using radiopaque contrast material injected through the urethra.
  - **Cystourethroscopy:** Direct visualization of the bladder and urethra by means of a flexible fiber-optic scope.
- Useful for helping to determine bladder and prostate size and the degree of kidney enlargement (if any) in patients with urinary retention or signs of renal insufficiency. Generally not indicated for the initial evaluation of uncomplicated lower urinary tract symptoms.
- Measures size of prostate and amount of residual urine, locates lesions unrelated to BPH. For client with elevated PSA levels, a TRUS-guided biopsy may be indicated.
- Prostate size and contour can be assessed, nodules evaluated, and areas of suspected malignancy detected; also helps determine pelvic floor tone and fluctuance, such as in prostate abscess, and pain and sensitivity of gland can be assessed.
- Results of this test will be abnormal if the bladder muscle is weak or urine flow is obstructed. Helps distinguish poor bladder contractility (detrusor underactivity) from BOO caused by prostate hyperplasia.
- Shows any blockage in the urinary tract causing delayed emptying of bladder, urinary retention, or presence of prostatic enlargement.
- May be used instead of intravenous pyelogram (IVP) to visualize bladder and urethra because it uses localized, rather than systemic, radiopaque contrast media.
- May be done in selected individuals. Shows degree of prostatic enlargement and bladder wall changes associated with bladder trabeculation.

**NURSING PRIORITIES**

1. Relieve acute urinary retention.
2. Promote comfort.
3. Prevent complications.
4. Assist client to deal with psychosocial concerns.
5. Provide information about disease process, prognosis, and treatment needs.

**DISCHARGE GOALS**

1. Voiding pattern normalized.
2. Pain or discomfort relieved.
3. Complications prevented or minimized.
4. Situation being dealt with realistically.
5. Disease process, prognosis, and therapeutic regimen understood.
6. Plan in place to meet needs after discharge.

**NURSING DIAGNOSIS:** [acute/chronic] urinary Retention**May Be Related To**

High urethral pressure; strong sphincter; blockage in urinary tract

**Possibly Evidenced By**

Sensation of bladder fullness; dribbling of urine; dysuria  
Small or frequent voiding  
Bladder distention; residual urine

**Desired Outcomes/Evaluation Criteria—Client Will****Urinary Elimination NIC**

Void in sufficient amounts with no palpable bladder distention.  
Demonstrate postvoid residuals of less than 50 mL, with absence of dribbling or overflow.

**ACTIONS/INTERVENTIONS****RATIONALE****Urinary Retention Care NIC***Independent*

Encourage client to void every 2 to 4 hours and when urge is noted.

May minimize urinary retention and overdistention of the bladder.

Ask client about stress incontinence when moving, sneezing, coughing, laughing, or lifting objects.

High urethral pressure inhibits bladder emptying or can inhibit voiding until abdominal pressure increases enough for urine to be involuntarily lost.

Observe urinary stream, noting size and force.

Useful in evaluating degree of obstruction and choice of intervention.

Have client document time and amount of each voiding.

Urinary retention increases pressure within the ureters and kidneys, which may cause renal insufficiency. Any deficit in blood flow to the kidney impairs its ability to filter and concentrate substances.

Note diminished urinary output. Measure specific gravity, as indicated.

A distended bladder can be felt in the suprapubic area.

Percuss and palpate suprapubic area.

Increased circulating fluid maintains renal perfusion and flushes kidneys, bladder, and ureters of sediment and bacteria. Note: Fluids may be restricted to prevent bladder distention if severe obstruction is present or until adequate urinary flow is reestablished.

Encourage oral fluids, if indicated.

Loss of kidney function results in decreased fluid elimination and accumulation of toxic wastes.

Monitor vital signs closely. Observe for hypertension, peripheral or dependent edema, and changes in mental status. Weigh daily. Maintain accurate intake and output (I&O).

Reduces risk of ascending infection.

Provide and encourage meticulous catheter and perineal care.

Promotes muscle relaxation, decreases edema, and may enhance voiding effort.

Recommend sitz bath, as indicated.

Medications have long been used as a first-line therapy for clients with mild to moderate symptoms.

**Collaborative**  
Administer medications, as indicated, for example:

(continues on page 690)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
5-alpha-reductase inhibitors (5-ARIs), such as dutasteride (Avodart); finasteride (Proscar)	Reduces the size of the prostate and decreases symptoms if taken long term; however, side effects, such as decreased libido and ejaculatory dysfunction, may influence client's choice for long-term use. Studies indicate that combination therapy with 5-ARI plus alpha blocker may be superior to taking either drug class alone for prevention of BPH progression (AUA, 2017).
Alpha-adrenergic antagonists, such as alfuzosin (Uro-Xatral), terazosin (Hytrin), doxazosin (Cardura), and tamsulosin (Flomax)	These agents block effects of postganglionic synapses that affect smooth muscle and exocrine glands. This action can decrease adverse urinary tract symptoms and increase urinary flow.
Phosphodiesterase-5 enzyme inhibitors, such as tadalafil (Cialis)	Bring about smooth muscle relaxation in the lower urinary tract, thus improving the symptoms of BPH (Deters et al, 2017).
Antibiotics and antibacterials	Given to combat infection. May be used prophylactically.
Catheterize for residual urine and leave indwelling catheter, as indicated.	Relieves and prevents urinary retention and rules out presence of ureteral stricture. Coudé catheter may be required because the curved tip eases passage of the tube around the enlarged prostate. Note: Bladder decompression should be done with caution to observe for signs of adverse reaction, such as hematuria due to rupture of blood vessels in the mucosa of the overdistended bladder and syncope due to excessive autonomic stimulation.
Monitor laboratory studies, such as the following:	
Blood urea nitrogen (BUN), creatinine (Cr), and electrolytes	Prostatic enlargement with obstruction eventually causes dilation of upper urinary tract, ureters, and kidneys, potentially impairing kidney function and leading to uremia.
Urinalysis and culture	Urinary stasis potentiates bacterial growth, increasing risk of urinary tract infection (UTI).
Prepare for and assist with urinary drainage, such as emergency cystostomy.	May be indicated to drain bladder during acute episode with azotemia or when surgery is contraindicated because of client's health status.
Prepare for minimally invasive therapies, such as:	
Heat therapies, such as laser treatment to destroy prostate tissue: transurethral microwave thermotherapy (TUMT), Cortherm, Prostatron, and transurethral needle ablation (TUNA)	These therapies rely on heat to cause destruction of prostatic tissue. Treatment is often completed in a one-time procedure carried out in the physician's office. Long-term outcomes are variable in terms of adequately treating urinary tract symptoms.
Prostatic urethral lift (PUL) implant	Treatment involves insertion of permanent implants into the prostate to retract the lobes away from the prostatic urethra. Note: A recent study comparing effectiveness of PUL with other procedures for BPH revealed that at 5 years, 86% of men did not require another procedure for BPH. The same study reported that for thermally based procedures, the 5-year retreatment rate ranges from 20% to 50%, and the annual retreatment rate for TURP is 1% to 2% (Bankhead, 2013; Krader, 2017).
Prepare for surgery as indicated.	Transurethral resection of the prostate (TURP) is the standard treatment for BOO secondary to BPH. Open prostatectomy is reserved for client with very large prostate ( $>75$ g) or with concomitant bladder stones or who cannot be positioned for transurethral surgery (Deters et al, 2017).

**NURSING DIAGNOSIS:** acute Pain**May Be Related To**

Physical injury agents—[mucosal irritation (e.g., bladder distention/urinary retention; urinary infection)]

**Possibly Evidenced By**

Self-report of pain intensity and characteristics using a standardized rating scale  
Guarding and protective behavior  
Expressive behaviors (e.g., restlessness, irritability)  
Self-focus/narrowed focus

**Desired Outcomes/Evaluation Criteria—Client Will****Pain Level NOC**

Report pain relieved or controlled.  
Appear relaxed.  
Be able to sleep and rest appropriately.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Pain Management: Acute NIC</b>	
<i>Independent</i>	
Assess pain, noting location, intensity (0 to 10 or similar coded scale), characteristics, and duration.	Provides information to aid in determining choice and effectiveness of interventions.
Provide comfort measures, such as back rub, helping client assume position of comfort. Suggest use of relaxation and deep-breathing exercises and diversional activities.	Promotes relaxation, refocuses attention, and may enhance coping abilities.
Encourage use of sitz baths and warm soaks to perineum.	Helps relax the smooth muscle in the prostate, easing the constriction of the urethra and bladder neck and increasing blood circulation to the pelvic region.
Ascertain that client is taking medications for BPH as prescribed. Document and discuss with physician if medication changes may be needed in medication regimen.	Client should be constant in taking prostate medications as prescribed to reduce swelling, improve urine flow, and prevent or treat urinary retention. The client should also avoid medications known to be associated with urinary retention (e.g., those that contain decongestants).
<i>Collaborative</i>	
Insert catheter and attach to straight drainage, as indicated. Maintain indwelling catheter when needed.	Draining bladder reduces acute bladder tension and irritability. Indwelling catheter may be needed in the short term for acute urinary retention or may be required long term for chronic retention.
Administer medications, as indicated, for example:	
Opioids, such as meperidine (Demerol)	Given to relieve severe pain; provide physical and mental relaxation.
Antibacterials, such as methenamine hippurate (Hiprex)	Reduces bacteria present in urinary tract and those introduced by drainage system.
Antispasmodics and bladder sedatives, such as flavoxate (Urispas) and oxybutynin (Ditropan)	Relieves bladder irritability.

**NURSING DIAGNOSIS:** risk for deficient Fluid Volume**Possibly Evidenced By**

Failure of regulatory mechanism (e.g., postobstructive diuresis from rapid drainage of a chronically overdistended bladder)

**Desired Outcomes/Evaluation Criteria—Client Will****Fluid Balance NOC**

Maintain adequate hydration as evidenced by stable vital signs, palpable peripheral pulses, adequate capillary refill, and moist mucous membranes.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Fluid Management</b> <b>NIC</b>	
<i>Independent</i>	
Monitor output carefully. Note outputs of 100 to 200 mL/hr.	Rapid or sustained diuresis could cause client's total fluid volume to become depleted and limits sodium reabsorption in renal tubules.
Encourage increased oral intake based on individual needs.	Client may have restricted oral intake in an attempt to control urinary symptoms, reducing homeostatic reserves and increasing risk of dehydration and hypovolemia.
Monitor BP and pulse. Evaluate capillary refill and oral mucous membranes.	Enables early detection of and intervention for systemic hypovolemia.
Promote bedrest with head elevated.	Decreases cardiac workload, facilitating circulatory homeostasis.
<i>Collaborative</i>	
Monitor electrolyte levels, especially sodium.	As fluid is pulled from extracellular spaces, sodium may follow the shift, causing hyponatremia.
Administer intravenous (IV) fluids—hypertonic saline as needed.	Replaces fluid and sodium losses to prevent or correct hypovolemia following outpatient procedures.

### NURSING DIAGNOSIS: Anxiety [specify level]

#### May Be Related To

Stressors/threat to current status (change in health status; threat to self-concept; threat to role function [e.g., concern about sexual ability])

#### Possibly Evidenced By

Increase in tension, apprehensiveness, uncertainty  
Worried about change in life event

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Anxiety Self-Control

Appear relaxed and report anxiety is reduced to a manageable level.  
Verbalize accurate knowledge of the situation.  
Demonstrate problem-solving skills.  
Uses resources/support systems effectively.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Anxiety Reduction</b> <b>NIC</b>	
<i>Independent</i>	
Be available to client. Establish trusting relationship with client and significant other (SO).	Demonstrates concern and willingness to help. Encourages discussion of sensitive subjects.
Provide information about specific procedures and tests and what to expect afterward, such as catheter, bloody urine, and bladder irritation. Be aware of how much information client wants.	Helps client understand purpose of what is being done and reduces concerns associated with the unknown, including fear of cancer. However, overload of information is not helpful and may increase anxiety.
Maintain matter-of-fact attitude in doing procedures and dealing with client. Protect client's privacy.	Communicates acceptance and eases client's embarrassment.
Encourage client and SO to verbalize concerns and feelings.	Defines the problem, providing opportunity to answer questions, clarify misconceptions, and problem-solve solutions.
Reinforce previous information client has been given.	Allows client to deal with reality and strengthens trust in caregivers and information presented.

**NURSING DIAGNOSIS:** **deficient Knowledge regarding condition, prognosis, treatment, self-care, and discharge needs**
**May Be Related To**

Insufficient information; insufficient interest in learning; misinformation presented by others  
Insufficient knowledge of resources

**Possibly Evidenced By**

Insufficient knowledge  
Inappropriate behaviors—apathetic, withdrawn  
Inaccurate follow-through of instruction or performance on a test or procedure  
Development of preventable complications

**Desired Outcomes/Evaluation Criteria—Client Will****Knowledge: Disease Process NOC**

Verbalize understanding of disease process, prognosis, and potential complications.  
Identify relationship of signs and symptoms to the disease process.  
Initiate necessary lifestyle or behavior changes.

**Knowledge: Treatment Regimen NOC**

Verbalize understanding of therapeutic needs.  
Participate in treatment regimen.  
Perform necessary procedures correctly.

**ACTIONS/INTERVENTIONS****RATIONALE****Teaching: Disease Process NIC***Independent*

Review disease process and client expectations.

Provides knowledge base from which client can make informed therapy choices. Note: "Watchful waiting" is one of the options in client with early BPH with no symptoms of urinary retention. Client should understand that this includes ongoing periodic evaluation for change.

Encourage verbalization of fears, feelings, and concerns.

Helping client work through feelings can be vital to rehabilitation.

Give information that the condition is not sexually transmitted.

May be an unspoken fear.

Review drug therapy, use of herbal products, and diet, such as increasing intake of fruits and soybeans.

Some clients may prefer to treat with complementary therapy because of decreased occurrence and lessened severity of side effects, such as impotence. Note: Nutrients known to inhibit prostate enlargement include zinc, soy protein, essential fatty acids, flaxseed, and lycopene. Herbal supplements that client may use include saw palmetto, pygeum, stinging nettle, and pumpkin seed oil. Note: A recent study found no difference in efficacy or side effects between saw palmetto and a placebo, indicating a need for further research as to benefit versus variability of potency or purity of botanical products (Martin, 2016).

Review usual medication regimen.

Medications known to be associated with urinary obstruction symptoms (e.g., tricyclic antidepressants, first-generation antihistamines, anticholinergic agents, diuretics, narcotics, and decongestants) may require dose adjustment or change to a different drug.

Encourage reading of labels and discuss concerns with over-the-counter (OTC) drugs.

Many OTC medications for upper respiratory symptom relief can increase urinary retention. Client with BPH should avoid these medications.

Recommend avoiding spicy foods, coffee, alcohol, long automobile rides, and rapid intake of fluids.

May cause prostatic irritation with resulting congestion. Sudden increase in urinary flow can cause bladder distention and loss of bladder tone, resulting in episodes of acute urinary retention.

(continues on page 694)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Address sexual concerns—during acute episodes of prostatitis, intercourse should be avoided but may be helpful in treatment of chronic condition.	Sexual activity can increase pain during acute episodes but may serve as massaging agent in presence of chronic disease. Note: Medications, such as finasteride (Proscar), are known to interfere with libido and erections. Alternatives include terazosin (Hytrin), doxazosin mesylate (Cardura), and tamsulosin (Flomax), which do not affect testosterone levels.
Provide information about sexual anatomy and function as it relates to prostatic enlargement. Encourage questions and promote a dialogue about concerns.	Having information about anatomy involved helps client understand the implications of proposed treatments because they might affect sexual performance.
Review signs and symptoms requiring medical evaluation—cloudy, odorous urine; diminished urinary output; inability to void; and presence of fever or chills.	Prompt interventions may prevent more serious complications.
Discuss necessity of notifying other healthcare providers of diagnosis.	Reduces risk of inappropriate therapy, such as the use of decongestants, anticholinergics, and antidepressants, which can increase urinary retention and may precipitate an acute episode.
Reinforce importance of medical follow-up for at least 6 months to 1 year, including rectal examination and urinalysis.	Recurrence of hyperplasia and infection caused by same or different organisms is not uncommon and requires changes in therapeutic regimen to prevent serious complications.
Discuss personal safety issues and potential environmental changes.	Recent research reports increased risk of falls in the presence of moderate to severe BPH associated with urgency, nocturia, and straining to void, with fall risk increasing with age and symptom severity (Parsons, 2010).

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

- **[acute/chronic] urinary Retention**—blockage [loss of bladder tone, decompensation of detrusor musculature]
- **risk for Infection**—urinary stasis, invasive procedure (periodic catheterization)
- **risk for ineffective Health Management**—perceived barriers

## PROSTATECTOMY

Prostatectomy includes a number of surgical procedures to remove part or all of the prostate gland and can be performed in several ways depending on the condition involved and the recommended treatment approach. When medical and minimally invasive options for benign prostatic hyperplasia (BPH) have been unsuccessful, more invasive treatment options may be considered, such as transurethral resection of the prostate (TURP) or open prostatectomy.

**Simple prostatectomy** removes part of the prostate and is generally recommended for men with severe urinary symptoms and very enlarged prostate gland (BPH) rather than cancer and can be performed open or robotically.

Prostatectomy for localized prostate cancer is often a **radical procedure**, removing not only the prostate but also surrounding lymph nodes and/or other structures. Prostatectomy may be used alone or in conjunction with chemotherapy, radiation, and hormone therapy. Transurethral procedures may be performed before open prostatectomy when urinary retention is occurring because of obstruction.

### I. Indications

- a. Benign prostatic hyperplasia (BPH)—related complications
  - i. Urinary retention
  - ii. Frequent urinary tract infections
  - iii. Bladder stones secondary to bladder outlet obstruction
  - iv. Recurrent gross hematuria
  - v. Kidney damage from longstanding blockage
  - vi. Failure to respond to medical or minimally invasive treatments
- b. Prostate cancer

### II. Procedures (AUA, 2014; Khera et al, 2015; Mayo Clinic Staff, 2017)

- a. Minimally invasive prostatectomy
  - i. Transurethral microwave thermotherapy (TUMT)
  - ii. Transurethral needle ablation (TUNA) using low-level frequency thermal energy
  - iii. Laser ablation: includes transurethral holmium laser ablation of the prostate (HoLAP), transurethral laser enucleation of the prostate (HoLEP), and holmium laser resection of the prostate (HoLRP)

- iv. Transurethral vaporization of the prostate (TUVP)
- v. Transurethral resection of the prostate (TURP)
  - 1. Most common procedure for the long-term treatment of BPH in client with moderate to severe lower urinary tract symptoms (LUTS) and/or where significantly bothered by these symptoms
  - 2. Obstructive prostatic tissue of the medial lobe surrounding the urethra is removed by means of a cystoscope introduced through the urethra.
- b. Open surgical approaches performed when the prostate is overly enlarged (greater than 75 g), the bladder has been damaged, or when there are complicating factors, such as cancer
  - i. Robot assisted—nerve sparing, uses a laparoscope, and several incisions are made in the abdomen
  - ii. Suprapubic prostatectomy—Obstructing prostatic tissue is removed through a low midline incision made through the bladder.
  - iii. Retropubic prostatectomy—Hypertrophied prostatic tissue mass located high in the pelvic region is removed through a low abdominal incision without opening the bladder.
  - iv. Perineal prostatectomy—Large prostatic masses low in the pelvic area are removed through an incision between the scrotum and the rectum.

### III. Statistics

- a. Morbidity: In 2010, 138,000 prostatectomy (for any diagnosis) procedures were performed in short-stay hospitals in the United States (Centers for Disease Control and Prevention [CDC], 2016). The most commonly performed procedures are prostatectomy and TURP, although numerous other less invasive procedures are on the rise (El-Hakim, 2010).
- b. Mortality: Prostatectomy is a relatively low-risk procedure (mortality stated as 0% or less than 1% and usually associated with cardiovascular disease) (Guilli et al, n.d.). The current 5-year survival rate for prostate cancer (stage dependent) is 98.6%, despite the fact that it was estimated that 26,730 would die of it in 2017 (National Cancer Institute, Surveillance, Epidemiology, and End Results Program [SEER], 2014).
- c. Cost: In 2017, the direct costs for treatment of prostate cancer totaled \$14.3 billion (NCI, 2018). A study of 1499 men who underwent robotic prostatectomy and 2565 men who had retropubic prostatectomy between 2008 and 2011 in Maryland reported that during that study period, the cost of a robotic prostatectomy averaged \$14,000 compared with \$10,100 for retropubic prostatectomy (Bankhead, 2012).

### GLOSSARY

**Continuous bladder irrigation (CBI):** Constant flow of normal saline or another bladder irrigant through a three-way urinary catheter to keep the catheter patent.

**Hematuria:** Blood in the urine.

**Kegel exercises:** Pelvic muscle exercises intended to improve pelvic muscle tone and prevent urine leakage.

**Retropubic:** Behind the pubic bone.

**Suprapubic:** Above the pubic bone.

**Transurethral resection of the prostate (TURP)**

**syndrome:** Rare complication directly related to this procedure. During the surgery, excess fluid collects in the body, reducing the concentration of sodium in the bloodstream. Common symptoms include nausea, vomiting, and confusion.

**Urinary retention:** Inability to empty bladder.

### CARE SETTING

Client is treated in short-stay inpatient acute surgical unit.

#### MAY EXHIBIT

## NURSING PRIORITIES

1. Maintain homeostasis and hemodynamic stability.
2. Promote comfort.
3. Prevent complications.
4. Provide information about surgical procedure, prognosis, treatment, and rehabilitation needs.

## DISCHARGE GOALS

1. Urinary flow restored or enhanced.
2. Pain relieved or controlled.
3. Complications prevented or minimized.
4. Procedure, prognosis, therapeutic regimen, and rehabilitation needs understood.
5. Plan in place to meet needs after discharge.

### NURSING DIAGNOSIS: **impaired urinary Elimination**

#### May Be Related To

Anatomic obstruction (e.g., blood clots, edema, trauma, surgical procedure)

#### Possibly Evidenced By

Frequency, urgency, hesitancy, dysuria

Incontinence; retention

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Urinary Elimination NOC

Void normal amounts without retention.

Demonstrate behaviors to regain bladder and urinary control.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Urinary Elimination Management NIC</b> <i>Independent</i>	
Assess urine output and catheter drainage system, especially during bladder irrigation after TURP.	Retention can occur because of edema of the surgical area, blood clots, and bladder spasms.
Assist client to assume normal position to void; for example, stand and walk to bathroom at frequent intervals after catheter is removed.	Encourages passage of urine and promotes sense of normality.
Record time, amount of voiding, and size of stream after catheter is removed. Note reports of bladder fullness, inability to void, and incontinence.	The catheter is usually removed 2 to 5 days after surgery, but voiding may continue to be a problem for some time because of urethral edema and loss of bladder tone. Urinary incontinence (associated with sphincter insufficiency and bladder dysfunction) is a common complication following prostate surgery and persists for varying lengths of time. Note: A review of two randomized trials of incontinent men postsurgery compared one-to-one sessions with a physical therapist to standard care and lifestyle advice only. High rates of incontinence persisted in both groups after 12 months. Pelvic floor muscle training after prostate surgery is unlikely to be effective (Glazner et al, 2011).
Encourage client to void when urge is noted but not more than every 2 to 4 hours per protocol.	Voiding with urge can reduce risk of urinary retention. However, limiting voids to every 4 hours, if tolerated, can increase bladder tone and aids in bladder retraining.
Encourage fluid intake to 2000 to 2500 mL as tolerated and if not contraindicated by cardiac or kidney disease. Limit evening fluids once catheter is removed.	Maintains adequate hydration and renal perfusion for urinary flow. “Scheduling” fluid intake reduces need to void during the night.
Instruct client in perineal exercises, trying to repeatedly stop and start urine stream several times a day.	Although not always successful in men after prostatectomy, exercise should be initiated to regain bladder sphincter control, in effort to minimize incontinence over time (Robinson, 2016; Sobol, 2016).
Advise client that “dribbling” is to be expected after catheter is removed and should resolve as recuperation progresses. Provide and instruct in use of continence pads when indicated.	Information can help client deal with and manage the problem.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<b>Collaborative</b>	
Maintain continuous bladder irrigation (CBI), as indicated, in early postoperative period.	Flushes bladder of blood clots and debris to maintain patency of the catheter and urinary flow.
Measure residual volumes via suprapubic catheter, if present, or with Doppler ultrasound.	Monitors effectiveness of bladder emptying. Residuals of more than 50 mL suggest need for continuation of catheter until bladder tone improves.

NURSING DIAGNOSIS: <b>risk for Bleeding</b>
<b>Possibly Evidenced By</b>
Treatment-related side effects (e.g., surgery—vascular nature of surgical area)
<b>Desired Outcomes/Evaluation Criteria—Client Will</b>
<b>Blood Loss Severity NOC</b>
Display no signs of active bleeding.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Bleeding Precautions NIC</b>	
<b>Independent</b>	
Monitor intake and output (I&O).	Indicator of fluid balance and replacement needs. With bladder irrigations, monitoring is essential for estimating blood loss and accurately assessing urine output. Note: Following release of urinary tract obstruction, marked diuresis may occur during initial recovery period.
Monitor vital signs, noting increased pulse and respiration, decreased blood pressure (BP), diaphoresis, pallor, delayed capillary refill, and dry mucous membranes.	If these symptoms are present, client may be hypovolemic due to overt or hidden hemorrhage. Hypovolemia requires prompt intervention to prevent impending shock. Note: Hypertension, bradycardia, and nausea or vomiting suggest TURP syndrome, requiring immediate medical intervention. TURP syndrome occurs because of fluid overload and hyponatremia associated with the use of large amounts of irrigation fluids flushing the bladder during surgery. If this solution is low in sodium, and the body absorbs too much of the fluid, the sodium level in the entire body can fall rapidly. Symptoms can occur within minutes to around 24 hours after surgery and can range from mild to life-threatening (Whitlock, 2017).
Investigate restlessness, confusion, and changes in behavior.	May reflect decreased cerebral perfusion (hypovolemia) or indicate cerebral edema from excessive solution absorbed into the venous sinusoids during TURP procedure (TURP syndrome).
Inspect dressings and wound drains. Weigh dressings, if indicated. Note hematoma formation.	Signs of persistent bleeding may be evident or sequestered within tissues of the perineum.
Encourage increased fluid intake, preferably water, to 2000 to 2500 mL/d unless contraindicated by medical condition.	Helps maintain circulating fluid volume.

<b>Bleeding Reduction NIC</b>	
Anchor urethral catheter and avoid excessive manipulation.	After TURP, the client will have special catheter in place that allows traction on the prostatic fossa to minimize bleeding. The catheter also allows irrigation of the bladder. Displacement of the catheter may cause bleeding. With bladder distention, clot formation may cause plugging of the catheter.

(continues on page 698)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Observe urethral and suprapubic catheter drainage, noting excessive or continued bleeding.	Bleeding is not unusual during first 24 hours for all but the perineal approach. Continued or heavy bleeding or recurrence of active bleeding requires medical evaluation and intervention.
Evaluate color, consistency of urine, for example:	
Bright red with bright red clots	Usually indicates arterial bleeding and requires aggressive therapy.
Dark burgundy with dark clots and increased viscosity	Suggests venous source, which is the most common type of bleeding and usually subsides on its own.
Bleeding with absence of clots	May indicate blood dyscrasias or systemic clotting problems.
Avoid taking rectal temperatures and use of rectal tubes or enemas.	May result in referred irritation to prostatic bed and increased pressure on prostatic capsule with risk of bleeding.
<b>Collaborative</b>	
Monitor laboratory studies, as indicated, such as:	
Hemoglobin/hematocrit (Hgb/Hct) and RBCs	Useful in evaluating blood losses and replacement needs.
Coagulation studies and platelet count	May indicate developing complications that can potentiate bleeding or clotting.
Serum sodium	Monitors for presence of hyponatremia.
Administer intravenous (IV) therapy or blood products, as indicated.	May need additional fluids, if oral intake inadequate, or blood products, if losses are excessive.
Maintain traction on indwelling catheter; tape catheter to inner thigh.	Traction on the 30-mL balloon positioned in the prostatic urethral fossa creates pressure on the arterial supply of the prostatic capsule to help prevent or control bleeding.
Release traction within 4 to 5 hours. Document period of application and release of traction, if used.	Prolonged traction may cause permanent trauma and problems with urinary control.
Administer stool softeners or laxatives, as indicated.	Prevention of constipation and straining for stool reduces risk of rectal-perineal bleeding.

## NURSING DIAGNOSIS: **risk for Infection**

### Possibly Evidenced By

Alteration in skin/tissue integrity—traumatized tissue, surgical incision, drains  
Invasive procedures (e.g., instrumentation during surgery, indwelling catheter, frequent bladder irrigation)

### Desired Outcomes/Evaluation Criteria—Client Will

#### Wound Healing: Primary Intention NOC

Experience no signs of infection.  
Achieve timely healing.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Infection Protection NIC</b>	
<b>Independent</b>	
Maintain sterile catheter system; provide regular catheter and urinary meatus care with soap and water, applying antibiotic ointment around catheter site per protocol.	Prevents introduction of bacteria and resultant infection.
Ambulate with drainage bag dependent.	Avoids backward reflux of urine, which may introduce bacteria into the bladder.
Monitor vital signs, noting low-grade fever, chills, rapid pulse and respiration, restlessness, irritability, and disorientation.	Client who has had TURP is at increased risk for surgical and septic shock related to instrumentation.
Observe drainage from wounds around suprapubic catheter.	Presence of drains and suprapubic incision increases risk of infection, as indicated by erythema or purulent drainage.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Change suprapubic/retropubic and perineal incision dressings frequently, cleaning and drying skin thoroughly each time.	Wet dressings cause skin irritation and provide medium for bacterial growth, increasing risk of wound infection.
Use ostomy-type skin barriers.	Provides protection for surrounding skin, preventing excoriation and reducing risk of infection.
<b>Collaborative</b> Administer antibiotics, as indicated.	May be given prophylactically because of increased risk of infection with prostatectomy.

NURSING DIAGNOSIS: acute Pain
<b>May Be Related To</b> Physical injury agents (e.g., operative procedure; irritation of bladder mucosa; reflex muscle spasm)
<b>Possibly Evidenced By</b> Self-report of pain intensity and characteristics using a standardized rating scale Guarding and protective behaviors Expressive behaviors—restlessness, irritability Self-focus Changes in vital signs
<b>Desired Outcomes/Evaluation Criteria—Client Will</b>
<p><b>Pain Level NOC</b> Report pain is relieved or controlled. Appear relaxed and sleep and rest appropriately.</p> <p><b>Pain Control NOC</b> Demonstrate use of relaxation skills and diversional activities, as indicated, for individual situation.</p>

ACTIONS/INTERVENTIONS	RATIONALE
<b>Pain Management: Acute NIC</b>	
<b>Independent</b>	
Assess pain, noting location, intensity (0 to 10 or similar coded scale), and characteristics.	Changes in pain reports may indicate developing complications requiring further evaluation and intervention. Note: Sharp, intermittent pain with urge to void and passage of urine around catheter suggests bladder spasms, which tend to be more severe with suprapubic or TURP approaches and usually decrease within 48 hours.
Maintain patency of catheter and drainage system. Keep tubing free of kinks and clots.	Maintaining a properly functioning catheter and drainage system decreases risk of bladder distention and spasm.
Promote intake of up to 3000 mL/d, as tolerated.	Decreases irritation by maintaining a constant flow of fluid over the bladder mucosa.
Give client accurate information about catheter, drainage, bladder spasms, and potential for voiding difficulties.	Allays anxiety and promotes cooperation with necessary procedures. Note: Depending on the degree of preoperative urge incontinence, postoperative urge incontinence may be present for weeks or months.
Provide comfort measures, such as position changes, back rub, Therapeutic Touch, and diversional activities. Encourage use of relaxation techniques, including deep-breathing exercises, visualization, and guided imagery.	Reduces muscle tension, refocuses attention, and may enhance coping abilities.
<b>Collaborative</b>	
Administer antispasmodics, such as:	
Oxybutynin (Ditropan), flavoxate (Urispas), B&O suppositories	Relaxes smooth muscle to provide relief of spasms and associated pain.
Propantheline bromide (Pro-Banthine)	Relieves bladder spasms by anticholinergic action. Usually discontinued 24 to 48 hours before anticipated removal of catheter to promote normal bladder contraction.

## NURSING DIAGNOSIS: risk for Sexual Dysfunction

### Possibly Evidenced By

Perceived sexual limitation; undesired change in sexual function  
Situational crisis—incontinence/leakage of urine, involvement of genital area  
Vulnerability (e.g., change in health status, threat to self-concept)

### Desired Outcomes/Evaluation Criteria—Client Will

#### Sexual Functioning NOC

Report understanding of sexual function and alterations that may occur following surgery.  
Discuss concerns about possible changes in body image and sexual functioning with partner/significant other (SO).  
Demonstrate problem-solving skills regarding solutions to difficulties that occur.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Sexual Counseling NIC</b> <i>Independent</i> Provide openings for client and SO to talk about concerns of incontinence and sexual functioning.	May have anxieties about the effects of surgery and may be hesitant about asking necessary questions. Anxiety may have affected ability to access information given previously.
Discuss basic anatomy. Be honest in answers to client's questions.	The nerve plexus that controls erection runs posteriorly to the prostate through the capsule. In procedures that do not involve the prostatic capsule, impotence and sterility are usually not consequences. Surgical procedure may not provide a permanent cure, and hypertrophy may recur.
Give accurate information about expectation of return of sexual function.	Physiological impotence occurs when the perineal nerves are cut during radical procedures; with other approaches, sexual activity can usually be resumed within weeks. If erectile dysfunction persists after healing is complete, client may want to pursue options to restore function—use of medications such as sildenafil citrate (Viagra). Note: Coincident erectile dysfunction and bladder neck contracture have been reported postoperatively in approximately 2% to 3% of patients following suprapubic prostatectomy (Khera et al, 2015).
Discuss retrograde ejaculation if transurethral or suprapubic approach is used.	Seminal fluid goes into the bladder and is excreted with the urine. This does not interfere with sexual functioning but will decrease fertility and cause urine to be cloudy. Note: Retrograde ejaculation has been reported in up to 80% to 90% of patients after surgery (Khera et al, 2015).
Instruct in perineal and pelvic floor exercises and interruption of urinary stream exercises.	Tightening pelvic floor muscles prior to standing, coughing, and sneezing promotes regaining bladder and, perhaps, erectile function.
<i>Collaborative</i> Refer to sexual counselor as indicated.	Persistent or unresolved problems may require professional intervention.

## NURSING DIAGNOSIS: deficient Knowledge regarding condition, prognosis, treatment, self-care, and discharge needs

### May Be Related To

Insufficient information or knowledge of resources; insufficient interests in learning; misinformation presented by others

### Possibly Evidenced By

Insufficient knowledge  
Inaccurate follow-through of instruction; development of preventable complications

<b>NURSING DIAGNOSIS:</b>	<b>deficient Knowledge regarding condition, prognosis, treatment, self-care, and discharge needs</b> (continued)
<b>Desired Outcomes/Evaluation Criteria—Client Will</b>	
<b>Knowledge: Disease Process NOC</b> Verbalize understanding of surgical procedure and potential complications. Initiate necessary lifestyle changes.	
<b>Knowledge: Treatment Regimen NOC</b> Verbalize understanding of therapeutic needs. Correctly perform necessary procedures and explain reasons for actions. Participate in therapeutic regimen.	

ACTIONS/INTERVENTIONS	RATIONALE
<b>Teaching: Disease Process NIC</b> <i>Independent</i> Review implications of procedure and future expectations.	Provides knowledge base from which client can make informed choices.
Emphasize necessity of good nutrition; encourage inclusion of fruits and increased fiber in diet.	Promotes healing and prevents constipation, reducing risk of postoperative bleeding.
Advise client to avoid or limit intake of caffeine, citrus juices, carbonated beverages, and spicy foods for first few weeks after surgery.	Acidic substances can lower urine pH, thereby aggravating dysuria.
Discuss initial activity restrictions, such as avoidance of heavy lifting, strenuous exercise, prolonged sitting, long car trips, and climbing more than two flights of stairs at a time.	Increased abdominal pressure and straining places stress on the bladder and prostate, potentiating risk of bleeding.
Encourage continuation of perineal exercises.	Facilitates urinary control and alleviation of incontinence.
Instruct in urinary catheter care if present. Identify source for supplies and support.	Promotes independence and competent self-care. Catheter may be in place only on day of surgery when laser procedure is done or for days to weeks with other procedures.
Instruct client to avoid tub baths after discharge.	Decreases the possibility of introduction of bacteria or undue tension on incision.
Review signs and symptoms requiring medical evaluation: erythema, purulent drainage from wound sites; inability to urinate, changes in character or amount of urine, presence of urgency or frequency; and heavy clots or bright red bleeding, fever, or chills.	Prompt intervention may prevent serious complications. Note: Urine may appear cloudy for several weeks until postoperative healing occurs and may appear cloudy after intercourse because of retrograde ejaculation.
Provide written information to client and SO regarding recovery expectations and home management, as indicated, regarding pain, incision care, and catheter-related problems and care.	Anxiety related to hospitalization, procedure performed, and associated diagnosis, fatigue, and postoperative pain often makes it difficult for client to absorb necessary self-care information.
Emphasize importance of follow-up care—evaluation by primary healthcare provider, urologist or oncologist, and laboratory studies.	Monitoring and follow-up can reduce incidence of unaddressed complications. Persistent incontinence and other postoperative issues will require additional evaluation and treatment.
Provide information on available community resources, such as home-health services, medical equipment supply company, housekeeping, and support persons.	Can be helpful in assisting client and SO in coping with challenges they are faced with following prostatectomy, whatever the reason for procedure—BPH, cancer, incontinence, and so forth.

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition, presence of complications, personal resources, and life responsibilities)

**In addition to surgical and cancer concerns:**

- **impaired urinary Elimination**—loss of bladder tone, possible discharge with catheter in place
- **Sexual Dysfunction**—situational crises (e.g., leakage of urine), altered body function (e.g., erectile dysfunction)

# Orthopedic Disorders

## FRACTURES

### I. Pathophysiology

- a. Discontinuity or break in a bone
  - b. May be associated with serious injury to nerves, blood vessels, muscles, and/or organs
- II. Etiology (Buckley & Page, 2016)**
- a. Common causes: Trauma, such as car crashes, falls, natural disasters, blunt force, and penetrating force. **P** Fractures are a common childhood injury and account for between 8% and 12% of all pediatric injuries (Flaherty et al, 2014; Rennie et al, 2007). Common mechanisms of injury in children with growth plate fractures include motor vehicle crashes (including pedestrians and cyclists), sports-related injuries, and falls.
  - b. Osteoporosis, which leaves bones thinned and weakened. Fractures of the spine, hip, or wrist are the most common types in persons with osteoporosis.
  - c. Repetitive stress, often associated with athletics (e.g., result of increasing amount or intensity of an activity too rapidly, improper equipment; increased physical stress, such as substantial increase in exercise time)
  - d. Bone tumors, can be malignant or benign
  - e. Infections, such as osteomyelitis; may be acute or chronic
  - f. The energy (high vs low) and velocity (speed) and direction of injury dictate the type and severity of fractures.

**III. Classifications (American Academy of Orthopedic Surgeons [AAOS], 2012; Walsh, 2011)**

- a. Location in the bone (e.g., proximal, midshaft, distal, through a joint)
- b. Types: (1) closed (also called simple) or open (formerly called compound), (2) complete (through the entire bone), (3) incomplete (the fracture does not go all the way through the bone), and (4) comminuted (broken into three or more parts [multifragmentary], where there is no contact between proximal and distal bone fragments).
- c. Fracture patterns: (1) spiral (from rotational force), (2) greenstick (one side of bone is broken and the other only bent), (3) oblique (angled fracture line), (4) transverse (horizontal fracture line), and (5) dislocated (fracture causes dislocation of part of joint, e.g., elbow, cervical vertebrae). **P** Note: Spiral fractures are common in toddlers from relatively minor trauma and can occur in older children from skiing and contact sports; greenstick

fractures occur most often during infancy and childhood when bones are soft.

- d. Open fractures are further classified as (Gustilo et al, 1990)
  - i) Type I (low-energy, simple fracture with wound opening less than 1 cm)
  - ii) Type II (also considered a low-energy injury, minimally contaminated, and without major soft-tissue damage or defect; with wound size greater than 1 cm)
  - iii) Type III (wound is longer than 1 cm; the mechanism often involves high-energy trauma, resulting in a severely unstable fracture with varying degrees of fragmentation and significant soft tissue disruption). Type III is further divided into subtypes:
    - (a) IIIA: Wound has enough healthy soft tissue to cover bone without need for skin graft coverage.
    - (b) IIIB: Disruption of soft tissues is extensive enough that skin grafting is necessary to cover bone; wound may be contaminated; multiple debridement procedures may be needed.
    - (c) IIIC: Open fracture is associated with vascular and neurologic injuries and requires vascular and plastic surgery.
- e. **P** The types of fractures typically occurring to children are Salter-Harris fractures, distal radius fractures (torus fractures and greenstick fractures), clavicular fractures, tibial shaft fractures, and radial head subluxation or nursemaid elbow. Salter-Harris classification: used for children and identifies where fracture is located relative to the growth plate: S = straight across; A = above growth plate; L = lower or below; T = through; ER = erasure of growth plate (crushed).

**IV. Phases of healing (Buckley & Page, 2016; Frost, 1989)**

- a. Reactive phase
  - i. Fracture and inflammatory phase: Bone fracture is an injury and thus incites an inflammatory response, which peaks 24 hr following the injury and is complete by the first week. Soon after fracture (3 to 5 days), the blood vessels constrict, stopping any further bleeding. During this stage, cellular signaling mechanisms work through chemotaxis and an inflammatory mechanism to attract the cells necessary to initiate the healing response.

- ii. Granulation tissue formation: Within 7 days, the body forms granulation tissue between the fracture fragments. This phase lasts about 2 weeks.
- b. Reparative phase
  - i. Callus formation: Cell proliferation and differentiation begin to produce osteoblasts and chondroblasts in the granulation tissue, synthesizing the extracellular organic matrices of woven bone and cartilage. Then the newly formed bone is mineralized. This stage requires 4 to 16 weeks, depending on the type and location of the fracture.
  - ii. Lamellar bone deposition: The meshlike callus of woven bone is replaced by a hard, rigid form of connective tissue (lamellar bone). Eventually, the woven bone and cartilage are replaced by trabecular bone (dense, hard, and slightly elastic connective tissue in which the fibers are impregnated with a form of calcium phosphate), restoring most of the bone's original strength. **P Pediatric fractures heal more quickly than adult fractures due to children's growth potential and a thicker, more active periosteum.**
- c. Remodeling phase
  - i. Trabecular bone is replaced by compact bone, remodeling to original bone contour.
  - ii. The final two stages can take several years in adults. **P Younger children have greater and more rapid remodeling potential.**

## V. Statistics

- a. Morbidity: In 2010, 671,000 Americans had open reduction for fractures listed on hospital discharge. **P Of those, 94,000 were under the age of 15 (Centers for Disease Control and Prevention [CDC], 2010).** The National Hospital Ambulatory Medical Care Survey for 2013 reported that fractures accounted for 3,300,831 visits to the emergency department in 2013.
- b. Mortality: Dependent upon multiple factors, including the specific bone affected, severity of fracture, associated soft tissue and organ involvement, age of individual, and presence of comorbidities. *Note:* Currently available mortality studies are associated with hip fractures (many related to the aging population and rising incidence of osteoporosis). Kim et al reported overall mortality rate of hip fractures as 15% to 20%, yet in older persons, this can increase to 36% over the year following hip fracture (Davenport, 2016; Kim et al, 2008).
- c. Cost: Because of the wide variety of fractures and treatment types and healthcare settings, no general figures are available about fractures. Figures are available regarding some very specific conditions and associated direct costs. For example, the estimated annual cost of hip fractures in 2009 in the United States ranged from \$10.3 to \$15.2 billion (LaBlanc et al, 2014). For a client without health insurance, surgical treatment of a broken leg typically costs \$17,000 to \$35,000, not including the surgeon's fee.

## G L O S S A R Y

- Buckle fracture:** Compression failure of bone that usually occurs at the junction of the metaphysis and the diaphysis. Commonly seen in distal radius.
- Closed fracture:** Fracture does not extend through the skin.
- Closed reduction:** Nonsurgical method for reduction and stabilization of fracture through a wide range of interventions, such as simple braces or aluminum splints, plaster or fiberglass casts, metal braces, and/or traction devices.
- Comminuted fracture:** Bone fragments into three or more pieces.
- Compartment syndrome:** Excessive swelling in the tissues associated with a fracture or crush injury to a limb, which elevates tissue pressure, resulting in decreased arteriovascular pressure and impaired tissue perfusion.
- Complete fracture:** Fracture line involves entire cross section of the bone, and bone fragments are usually displaced.
- Compression fracture:** Collapsing of bone usually involves vertebra of the thoracic or lumbar spine and is often seen in elderly people as a result of osteoporosis but may also occur traumatically.
- Crepitation:** Grating sound heard with movement of ends of fractured bones.
- Fragility fracture:** Fractures secondary to osteoporosis.
- Incomplete or greenstick fracture:** Involves only a portion of the cross section of the bone; one side breaks and the other usually just bends.
- Obligate fracture:** Break occurs diagonally.
- Open fracture:** Bone fragments extend through the muscle and skin and are potentially infected.

**Open reduction:** Surgical method for stabilization of a fracture using rods, pins, screws, and plates.

**Pathological fracture:** Fracture occurs in diseased bone—such as in cancer and osteoporosis—with no (spontaneous) or only minimal trauma.

**P Pediatric long bones:** Three main regions: epiphysis—each end of a long bone with associated joint cartilage; physis [growth plate]—cartilage cells that create solid bone with growth; and metaphysis—wide area below the physis, closest to the diaphysis/shaft.

**Periosteum:** Membrane that lines the outer surface of all bones, except at the joints of long bones, and serves as the attachment mechanism for muscles and tendons.

**P Physeal fractures:** Growth plate (physeal) fractures are defined as disruptions in the cartilaginous physis of long bones that may or may not involve epiphyseal or metaphyseal bone (Jones et al, 2017). There are two growth plates in immature long bones: the **horizontal** growth plate (physis) and the **spherical** growth plate (enables epiphyseal growth) (Rabin, 2017).

**P Plastic deformation:** The bone is angulated beyond its elastic limit, but the energy is insufficient to produce a fracture. No fracture line is visible radiographically. Unique to children. Most commonly seen in the ulna, occasionally in the fibula.

**Remodeling:** Stage in which fracture healing is completed (i.e., bone is restored to its original shape, structure, and mechanical strength). Remodeling of the bone occurs slowly over months to years.

(continues on page 704)

## G L O S S A R Y (continued)

**P** **Salter-Harris fracture:** Common fracture that occurs in growth plate in children. There are five types of Salter-Harris growth plate fractures. *Note:* An estimated 75% of all physeal fractures are type 2 and the most common physeal fracture in children (Rabin, 2017; Wound Care Society, 2016).

**Simple fracture:** Bone breaks into two pieces.

**Spiral fracture:** Break follows a helical line along and around the bone; commonly associated with a twisting motion.

**Stress fracture:** Hairline fracture due to overuse or repeated microtrauma, such as those seen in gymnasts, runners, and tennis or basketball players, as well as those who participate in marching bands or drill teams.

**Transverse fracture:** Break occurs in a straight line across the bone.

## CARE SETTING

Many fractures are managed at the community level. Although many of the interventions listed here are appropriate for this population, this plan of care addresses more complicated injuries encountered on an inpatient acute medical-surgical unit. *Note:* Definitive treatment of fractures may be delayed until life-threatening injuries, such as lung contusions, brain injury, or hemodynamic instability, have been stabilized

## CLIENT ASSESSMENT DATABASE

Symptoms of fracture depend on the site, severity, type, and amount of damage to other structures.

### DIAGNOSTIC DIVISION MAY REPORT

#### ACTIVITY/REST

- Weakness
- Fatigue
- Gait and/or mobility problems

### MAY EXHIBIT

- Restriction or loss of function of affected part—may be immediate, because of the fracture, or develop secondarily from tissue swelling, pain
- Weakness of affected extremity
- Range-of-motion (ROM) deficits
- Discrepancy in limb length

#### CIRCULATION

- Hypertension—occasionally seen as a response to acute pain or anxiety, or hypotension from severe blood loss
- Tachycardia—stress response, hypovolemia
- Pulse diminished or absent distal to injury in extremity
- Pallor of affected part
- Tissue swelling
- Bruising or hematoma mass at site of injury

#### ELIMINATION

- Hematuria
- Changes in output—acute renal failure (ARF) with major skeletal muscle damage

**MAY REPORT (continued)****MAY EXHIBIT (continued)****NEUROSENSORY**

- Loss of or impaired motion or sensation
- Muscle spasms worsening over time
- Numbness or tingling (paresthesias)

**PAIN/DISCOMFORT**

- Sudden severe pain at time of injury—may be localized to the area of tissue or skeletal damage and then become more diffuse; however, can diminish on immobilization
- Absence of pain—suggests nerve damage
- Muscle-aching pain
- Muscle spasms or cramping following immobilization

**SAFETY**

- Use of alcohol or other drugs
- Circumstances of incident may not support type of injury incurred—may be suggestive of abuse

**TEACHING/LEARNING**

- Use of multiple medications—prescribed and/or over-the-counter (OTC) with interactive effects

**DISCHARGE PLAN CONSIDERATIONS**

- May require temporary assistance with transportation, self-care activities, and homemaker or maintenance tasks
- May require additional therapy or rehabilitation postdischarge
- Possible placement in assisted living or extended-care facility for a period of time

► Refer to section at end of plan for postdischarge considerations.

- Local musculoskeletal deformities—abnormal angulation, posture changes, shortening of limbs, rotation, or crepitus
- Giving way or collapse, locking of joints, dislocations
- Muscle spasms
- Visible weakness or loss of function

- Guarding or distraction behaviors
- Restlessness, irritability, moaning, crying
- Self-focus

- Skin lacerations
- Tissue avulsion
- Bleeding
- Color changes of skin
- Presence of risk factors for falling—age, osteoporosis, dementia, arthritis, other chronic conditions; preexisting unrecognized fracture

**DIAGNOSTIC STUDIES****TEST****WHY IT IS DONE**

- **Radiographic examinations:** First-line tool to determine location and extent of fractures/trauma and bone alignment.
- **Bone scans, tomograms, computed tomography (CT), and magnetic resonance imaging (MRI) scans:** Used to visualize changes of structure within the body and bone alignment. May be preferred diagnostic tool because of superior ability to image some types of injuries.
- **Bone densitometry:** Photons from a single- or dual-emitting source are used to measure comparative density of the spine, femur, or distal radius. These are then compared with normal values for a large patient population based on sex and age.

**WHAT IT TELLS ME**

May reveal preexisting and yet undiagnosed fracture(s).

These are used to visualize fractures, bleeding, and soft tissue damage; they differentiate between stress or trauma fractures and bone neoplasms.

Procedure may be done if fracture is suspected or known to be associated with osteoporosis. Note: Osteoporosis is often underrecognized and undertreated, and clients with fragility fractures secondary to osteoporosis are at risk of recurrent fracture (Inderjeeth et al, 2006).

(continues on page 706)

## DIAGNOSTIC STUDIES (contd.)

WHY IT IS DONE (continued)	WHAT IT TELLS ME (continued)
<ul style="list-style-type: none"><li><b>Arteriograms:</b> X-rays that use contrast media to evaluate arterial blood flow.</li><li><b>Complete blood count (CBC):</b> Battery of screening tests, which typically includes hemoglobin (Hgb); hematocrit (Hct); red blood cell (RBC) count, morphology, indices, and distribution width index; platelet count and size; white blood cell (WBC) count and differential.</li><li><b>Urine creatinine (Cr) clearance:</b> Measures filtering ability of the kidneys.</li><li><b>Coagulation profile:</b> Tests that measure blood coagulation. There are many types of coagulation tests, some of which are general and tell only whether a person's blood is clotting normally. Other tests can identify which element within the blood is causing abnormal clotting.</li></ul>	May reveal vascular damage.  Hct may be increased, reflecting hemoconcentration or dehydration, or Hct may be decreased, signifying hemorrhage at the fracture site or at distant organs in multiple trauma. Increased WBC count is a normal stress response after trauma.  Muscle trauma increases Cr load for renal clearance; decreased renal perfusion or impaired renal function also elevates Cr. Alterations may occur because of blood loss, multiple transfusions, or liver injury.

### NURSING PRIORITIES

1. Prevent further bone/tissue injury.
2. Alleviate pain.
3. Prevent complications.
4. Provide information about condition, prognosis, and treatment needs.

### DISCHARGE GOALS

1. Fracture stabilized.
2. Pain controlled.
3. Complications prevented or minimized.
4. Condition, prognosis, and therapeutic regimen understood.
5. Plan in place to meet needs after discharge.

### NURSING DIAGNOSIS: risk for Injury [additional]

#### Possibly Evidenced By

Physical (e.g., loss of skeletal integrity [fractures]; movement of bone fragments)

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Bone Healing NOC

Maintain stabilization and alignment of fracture(s).  
Display callus formation/beginning union at fracture site as appropriate.

##### Risk Control NOC

Demonstrate body mechanics that promote stability at fracture site.

### ACTIONS/INTERVENTIONS

### RATIONALE

#### Positioning NIC

##### Independent

Ascertain type of fracture injury and medical treatment planned if surgery is not indicated.

Nonoperative (closed) therapy consists of immobilization through splinting, casting (fiberglass or plaster of Paris), or traction apparatus (skin and skeletal traction). Closed reduction is performed initially for any fracture that is displaced, shortened, or angulated. This is achieved by applying force (traction) to the long axis of the injured bone (usually femur) and then reversing the mechanism of injury/fracture. Note: With the advancement of orthopedic implant technology and operative techniques, traction is rarely used for definitive fracture/dislocation management (Buckley & Page, 2016).

Maintain bedrest or limb rest as indicated. Provide support of joints above and below fracture site, especially when moving and turning.

Provides stability, reducing possibility of disturbing alignment and aggravating muscle spasms, which enhances healing.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<b>Cast Care: Wet (if cast is made of plaster of Paris) NIC</b> Support fracture site with pillows or folded blankets. Maintain neutral position of affected part with sandbags, splints, trochanter roll, or footboard.	Prevents unnecessary movement and disruption of alignment. Proper placement of pillows also can prevent pressure deformities in the drying cast.
Use the palms of the hands, not the fingertips, when touching the wet cast.	Fingertips can dent the cast before it is dry.
Obtain sufficient personnel for turning. Avoid using abduction bar for turning client with spica cast.	Hip, body, or multiple casts can be extremely heavy and cumbersome. Failure to properly support limbs in casts may cause damage to cast or injury to client and staff.
<b>Traction/Immobilization Care NIC</b> Evaluate splinted extremity for edema resolution.	Cocaptation splint (e.g., Jones-Sugar tong) may be used to provide immobilization of fracture while excessive tissue swelling is present. As edema subsides, readjustment of splint or application of fiberglass or plaster cast may be required for continued alignment of stable fracture.
Maintain position and integrity of traction apparatus, when used.	Traction is a less frequently used modality than in times past <b>P</b> but may still be used in some instances of femur fracture in children and older adults or clients with multitrauma who are not current candidates for surgery. Traction permits pull on the long axis of the fractured bone and overcomes muscle tension and shortening to facilitate alignment and union. Skeletal traction using pins, wires, or tongs permits use of greater weight for traction pull than can be applied to skin tissues.
Assess integrity of external fixator device.	<b>P</b> External fixation has evolved from being used primarily as a last-resort fixation method to becoming a mainstream technique used to treat a great many bone and soft tissue pathologies in both adults and children. This device provides stabilization and rigid support for fractured bone without use of ropes, pulleys, or weights, thus allowing for greater client mobility and comfort and facilitating wound care.
<b>Collaborative</b> Review follow-up or serial x-rays.	Provides visual evidence of proper alignment or beginning callus formation and healing process to determine level of activity and need for changes in, or additions to, the therapy plan.
Prepare client for surgery where indicated.	Surgical procedures may include open reduction and internal fixation (ORIF); flexible or rigid intramedullary nailing; insertion of plates, screws, and pins. Treatments are variable and dependent on the type, location, and severity of fracture and other internal injuries.
Initiate and maintain bone rehabilitation—early ambulation, weight-bearing activities, soft tissue massage, or electrical stimulation if used.	Promotes bone growth and healing.
<b>NURSING DIAGNOSIS:</b> <b>acute Pain</b> <b>May Be Related To</b> Physical injury agents [e.g., muscle spasms, movement of bone fragments, soft tissue injury, traction/immobility device] <b>Possibly Evidenced By</b> Self-report of intensity and characterizes of pain using standardized pain scale/instrument Self-focused/narrowed focus; facial expression of pain Guarding/protective behavior Changes in vital signs	(continues on page 708)

**NURSING DIAGNOSIS:** **acute Pain** (continued)**Desired Outcomes/Evaluation Criteria—Client Will****Pain Level NOC**

Report pain is relieved or controlled.

Display relaxed manner, able to participate in activities, and sleep and rest appropriately.

**Pain Control NOC**

Demonstrate use of relaxation skills and diversional activities, as indicated for individual situation.

**ACTIONS/INTERVENTIONS****RATIONALE****Pain Management: Acute NIC***Independent*

Maintain immobilization of affected part by means of bedrest, cast, splint, and traction. (Refer to ND: risk for Injury [additional].)

Relieves pain and prevents bone displacement/extension of tissue injury.

Elevate and support injured extremity.

Promotes venous return, decreases edema, and may reduce pain.

Avoid use of plastic sheets/pillows under limbs in cast.

Can increase discomfort by enhancing heat production in the drying cast.

Elevate bed covers and keep linens off toes.

Maintains body warmth without discomfort due to pressure of bedclothes on affected parts.

Evaluate and document reports of pain or discomfort, noting location and characteristics, including intensity (0 to 10, or similar age appropriate coded scale), relieving, and aggravating factors. Note nonverbal pain cues, such as changes in vital signs and emotions or behavior. Listen to reports of family member/significant other (SO) regarding client's pain.

Influences choice of, and monitors effectiveness of, interventions. Many factors, including level of anxiety, may affect perception of and reaction to pain. Note: Absence of pain expression does not necessarily mean lack of pain.

Encourage client to discuss problems related to injury.

Helps alleviate anxiety. Client may feel need to relive the accident experience.

Explain procedures before beginning them.

Allows client to prepare mentally for activity and to participate in controlling level of discomfort.

Medicate before care activities. Let client know it is important to request medication before pain becomes severe.

Promotes muscle relaxation and enhances participation.

Perform and supervise passive or active ROM exercises.

Maintains strength and mobility of unaffected muscles and facilitates resolution of inflammation in injured tissues.

Provide alternative comfort measures, for example, massage, back rub, or position changes.

Improves general circulation; reduces areas of local pressure and muscle fatigue.

Provide emotional support and encourage use of stress management techniques—progressive relaxation, deep-breathing exercises, and visualization or guided imagery; provide Therapeutic Touch.

Refocuses attention, promotes sense of control, and may enhance coping abilities in the management of the stress of traumatic injury and pain, which is likely to persist for an extended period.

Identify diversional activities appropriate for client's age, physical abilities, and personal preferences.

Prevents boredom, reduces muscle tension, and can increase muscle strength; may also enhance coping abilities.

Investigate any reports of unusual or sudden pain or deep, progressive, and poorly localized pain unrelieved by analgesics.

May signal developing complications, such as infection, tissue ischemia, or compartment syndrome. (Refer to ND: risk for peripheral Neurovascular Dysfunction, following.)

*Collaborative*

Apply cold or ice pack first 24 to 72 hours and as necessary per facility policy or protocol.

Reduces edema and hematoma formation; decreases pain sensation. Note: Length of application depends on degree of client comfort and whether the skin is carefully protected.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Administer medications, as indicated: opioid and nonopioid analgesics, such as morphine, meperidine (Demerol), or hydrocodone (Vicodin); injectable and oral nonsteroidal anti-inflammatory drugs (NSAIDs), such as ketorolac (Toradol) or ibuprofen (Motrin); and/or muscle relaxants, such as cyclobenzaprine (Flexeril) or carisoprodol (Soma).	Given to reduce pain and/or muscle spasms.
Maintain continuous intravenous (IV) or patient-controlled analgesia (PCA) using peripheral, epidural, or intrathecal routes of administration. Maintain safe and effective infusions and equipment.	Optimal pain management is essential to permit early mobilization and physical therapy and to maintain adequate blood level of analgesia, preventing fluctuations in pain relief with associated muscle tension or spasms.

NURSING DIAGNOSIS:	risk for peripheral Neurovascular Dysfunction
<b>Possibly Evidenced By</b>	
Fractures; trauma; orthopedic surgery; immobilization Vascular obstruction Mechanical compression (e.g., cast, dressing)	
<b>Desired Outcomes/Evaluation Criteria—Client Will</b>	
<b>Tissue Perfusion: Peripheral NOC</b>	Maintain function as evidenced by absence of pallor and palpable pulses, movement, and sensation (CMS) within normal range for individual.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Circulatory Precautions NIC</b>	
<i>Independent</i>	
Assess client's risk for development of venous thromboembolism (VTE) and acute compartment syndrome (ACS).	Any client with severe fractures or multiple fractures, especially of long bones (femur), is at risk for VTE (including deep vein thrombosis [DVT] and pulmonary embolus [PE], particularly if long-term bedrest is required). Clients with fractures of tibia or femur can be at risk for ACS if they have sustained severe tissue injury that resulted in significant bleeding into a closed compartment, compressed blood vessels such as might occur with a crush injury, or surgery to repair blood vessels with subsequent reperfusion to a compartment. ACS can also be a complication of circumferential dressings, splints, or casts that are applied too tightly (Walsh, 2011; Wedro, 2016).
Remove jewelry from affected limb immediately.	May restrict circulation when edema occurs.
Evaluate presence and quality of peripheral pulse distal to injury via palpation or Doppler. Compare with uninjured limb.	Decreased or absent pulse may reflect vascular injury and necessitates immediate medical evaluation of circulatory status. Be aware that occasionally a pulse may be palpated even though circulation is blocked by a soft clot through which pulsations may be felt. In addition, perfusion through larger arteries may continue after increased compartment pressure has collapsed the arteriole and venule circulation in the muscle.
Assess capillary return, skin color, and warmth distal to the fracture.	Return of color should be rapid (3–5 seconds in adults—time slows with age, and  <2 seconds in infants/children). White, cool skin indicates arterial impairment. Cyanosis suggests venous impairment. Note: Peripheral pulses, capillary refill, skin color, and sensation may be normal even in the presence of compartment syndrome because superficial circulation is usually not compromised.

(continues on page 710)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Monitor vital signs. Note signs of general pallor or cyanosis, cool skin, and changes in mentation.	Inadequate circulating volume compromises systemic tissue perfusion.
Test stools and gastric aspirant for occult blood. Note continued bleeding at trauma or injection site(s) and oozing from mucous membranes.	Increased incidence of gastric bleeding accompanies fractures and trauma and may be related to stress or occasionally reflects a clotting disorder requiring further evaluation.
<b>Circulatory Care: Arterial [or] Venous Insufficiency NIC</b> Maintain elevation of injured extremity(ies) unless contraindicated by confirmed presence of compartment syndrome.	Promotes venous drainage and decreases edema. Note: In presence of increased compartment pressure, elevation of the extremity actually impedes arterial flow, decreasing perfusion. Casts or circumferential dressings can also cause arterial venous insufficiency.
Assess entire length of injured extremity for swelling and edema formation. Measure injured extremity and compare with uninjured extremity. Note appearance and spread of hematoma.	Increasing circumference of injured extremity may suggest general tissue swelling or edema but may also reflect hemorrhage. Note: A 1-inch increase in an adult thigh can equal approximately 1 unit of sequestered blood.
Note reports of pain extreme for type of injury or increasing pain on passive movement of extremity, development of paresthesia, muscle tension or tenderness with erythema, and change in pulse quality distal to injury. Do not elevate extremity. Report symptoms to physician at once.	Continued bleeding or edema formation within a muscle enclosed by tight fascia can result in impaired blood flow and ischemic myositis or compartment syndrome, necessitating emergency interventions to relieve pressure and restore circulation.
Investigate sudden signs of limb ischemia, such as decreased skin temperature, pallor, and increased pain.	Fracture dislocations of joints, especially the knee, may cause damage to adjacent arteries, with resulting loss of distal blood flow.
Encourage client to routinely exercise digits or joints distal to injury. Ambulate as soon as possible.	Enhances circulation and reduces pooling of blood, especially in the lower extremities.
Investigate tenderness, swelling, redness, or tissue pain on dorsiflexion of foot (positive Homans' sign).	There is an increased potential for thrombophlebitis and pulmonary emboli in clients who have been immobile for several days. Note: The absence of a positive Homans' sign is not a reliable indicator in many people. Refer to CP: Venous Thromboembolism (VTE) Disease including Deep Vein Thrombosis (DVT) and Pulmonary Embolism (PE), as indicated.
Perform neurovascular assessments, noting changes in motor and sensory function. Ask client to localize pain or discomfort.	Impaired feeling, numbness, tingling, and increased or diffuse pain occur when circulation to nerves is inadequate or nerves are damaged.
Test sensation of peroneal nerve by pinch or pinprick in the dorsal web between the first and second toe, and assess ability to dorsiflex toes, if indicated.	Length and position of peroneal nerve increase risk of its injury in the presence of leg fracture, edema, or compartment syndrome or because of malposition of traction apparatus.
<b>Cast Care: Maintenance NIC</b> Assess tissues around cast edges for rough places and pressure points. Investigate reports of "burning sensation" under cast.	These factors may be the cause of or be indicative of tissue pressure or ischemia, leading to breakdown and necrosis.
Monitor position and location of supporting ring of splints or sling.	Traction apparatus can cause pressure on vessels and nerves, particularly in the axilla and groin, resulting in ischemia and possible permanent nerve damage.
<b>Circulatory Care: Arterial [or] Venous Insufficiency NIC Collaborative</b> Apply ice bags around fracture site for short periods of time on an intermittent basis for 24 to 72 hours.	Reduces edema and hematoma formation, which could impair circulation. Note: Length of application of cold therapy is usually 20 to 30 minutes at a time.
Monitor Hgb/Hct and coagulation studies, such as pro-thrombin time (PT).	Assists in calculation of blood loss and needs and effectiveness of replacement therapy. Coagulation deficits may occur secondary to major trauma, in presence of fat emboli, or during anticoagulant therapy.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Administer IV fluids and blood products as needed.	Maintains circulating volume, enhancing tissue perfusion.
Administer medications, as indicated: low-molecular-weight heparin or heparinoids, such as enoxaparin (Lovenox), dalteparin (Fragmin), or fondaparinux (Arixtra), if indicated.	Anticoagulants may be given prophylactically to reduce threat of deep venous thrombus.
Apply antiembolic hose or sequential pressure hose or compression boots, as indicated.	Decreases venous pooling and may enhance venous return, thereby reducing risk of thrombus formation.
Split or bivalve cast as needed. Be sure to cut through wadding down to the skin.	May be done on an emergency basis to relieve restriction and improve impaired circulation resulting from compression and edema formation in injured extremity. The wadding under the cast may also be restrictive.
Refer for and monitor intracompartmental pressures as appropriate.	Diagnosis of compartment syndrome is typically performed with client under light or local anesthesia and measured by means of slit catheter or side-ported catheter. Compartment pressure must be interpreted within the context of the overall clinical picture. However, some practitioners believe that absolute pressure measurement of 30 mm Hg in the compartment should be the “critical pressure” for recommending fasciotomy (Jagminas, 2017).
Prepare for surgical intervention, such as fasciotomy, as indicated.	Failure to relieve pressure or correct compartment syndrome within 4 to 6 hours of onset can result in severe contractures, loss of function, and disfigurement of extremity distal to injury, possibly necessitating amputation.

### NURSING DIAGNOSIS: risk for impaired Gas Exchange

#### Possibly Evidenced By

Ventilation-perfusion imbalance (e.g., altered blood flow, blood or fat emboli)  
Alveolar and capillary membrane changes (e.g., interstitial congestion, pulmonary edema)

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Respiratory Status: Gas Exchange NOC

Maintain adequate respiratory function, as evidenced by absence of dyspnea or cyanosis; respiratory rate and arterial blood gases (ABGs) are within client's normal range.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Respiratory Monitoring NIC</b> <i>Independent</i> Monitor respiratory rate and effort. Note stridor, use of accessory muscles, retractions, and development of central cyanosis.	Tachypnea, dyspnea, and changes in mentation are early signs of respiratory insufficiency and may be the only indicator of developing pulmonary emboli in the early stage. Remaining signs and symptoms reflect advanced respiratory distress and impending failure.
Auscultate breath sounds, noting development of unequal, hyperresonant sounds; also note presence of crackles, rhonchi, or wheezes and inspiratory crowing or croupy sounds.	Changes in or presence of adventitious breath sounds reflect developing respiratory complications—atelectasis, pneumonia, emboli, or acute respiratory distress syndrome (ARDS). Note: Early fixation of long-bone fractures (within 24 hours of injury) can reduce client's risk of developing ARDS (Walsh, 2011). Inspiratory crowing reflects upper airway edema and is suggestive of fat emboli as a reason for ARDS. Note: Fat embolus syndrome (FES) should be suspected in client with long-bone fractures who develops hypoxia, fever, bilateral pulmonary infiltrates, and a rash (Bulauitan & Gupta, 2017).

(continues on page 712)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Instruct and assist with deep-breathing and coughing exercises. Reposition frequently.	Promotes alveolar ventilation and perfusion. Repositioning promotes drainage of secretions and decreases congestion in dependent lung areas.
Note increasing restlessness, confusion, lethargy, or stupor.	Impaired gas exchange or presence of pulmonary emboli can cause deterioration in client's level of consciousness as hypoxemia and acidosis develop.
Observe sputum for signs of blood.	Hemoptysis may occur with pulmonary emboli.
Inspect skin for petechiae above nipple line, in axilla, spreading to abdomen or trunk, buccal mucosa and hard palate, and conjunctival sacs and retina.	This is the most characteristic sign of fat emboli, which may appear within 2 to 3 days after injury.
<b>Collaborative</b>	
Instruct in, and encourage regular use of, incentive spirometry.	Maximizes ventilation and minimizes atelectasis.
Administer supplemental oxygen, if indicated.	Increases available O <sub>2</sub> for optimal tissue oxygenation.
Monitor laboratory studies, such as the following:	
Pulse oximetry or serial ABGs	Identifies situations in which oxygen desaturation is occurring and reveals complications such as impaired gas exchange and developing respiratory failure.
Hgb, calcium, erythrocyte sedimentation rate (ESR), serum lipase, fat screen, and platelets, as appropriate	Anemia, hypocalcemia, elevated ESR and lipase levels; fat globules in blood, urine, or sputum; and decreased platelet count (thrombocytopenia) are often associated with fat emboli.
Administer medications, as indicated, for example:	
Low-molecular-weight heparin or heparinoids, such as enoxaparin (Lovenox), dalteparin (Fragmin), or fondaparinux (Arixtra)	Used for prevention of thromboembolic phenomena, including deep vein thrombosis and pulmonary emboli.
Corticosteroids	Steroids have been used with some success to prevent and treat fat embolus.

## NURSING DIAGNOSIS: **impaired physical Mobility**

### May Be Related To

Alteration in bone structure integrity; neuromuscular, musculoskeletal, or sensory-perceptual impairment  
Decrease in muscle mass, strength, or control; disuse  
Pain; reluctance to initiate movement  
Prescribed movement restrictions—limb immobilization

### Possibly Evidenced By

Discomfort  
Decrease in range of motion; slowed movement; alteration in gait

### Desired Outcomes/Evaluation Criteria—Client Will

#### Skeletal Function NOC

Maintain position of function.  
Maintain or increase strength and function of affected and compensatory body part.

#### Mobility NOC

Regain and maintain mobility at the highest possible level.  
Demonstrate techniques that enable resumption of activities, especially activities of daily living (ADLs).

ACTIONS/INTERVENTIONS	RATIONALE
<b>Bedrest Care NIC</b>	
<b>Independent</b>	
Assess degree of immobility produced by injury and/or treatment and note client's perception of immobility.	Client may be restricted by self-view or self-perception out of proportion with actual physical limitations, requiring information and interventions to promote progress toward wellness.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Encourage participation in diversional or recreational activities. Maintain stimulating environment—computer/tablet, TV, music, personal possessions, clock, calendar, and visits from family and friends.	Provides opportunity for release of energy, refocuses attention, enhances client's sense of self-control and self-worth, and aids in reducing social isolation.
Instruct client in active, or assist with passive, ROM exercises of affected and unaffected extremities.	Increases blood flow to muscles and bone to improve muscle tone, maintain joint mobility, and prevent contractures, atrophy, and calcium resorption from disuse.
Encourage use of isometric exercises, starting with the unaffected limb.	Isometrics contract muscles without bending joints or moving limbs and help maintain muscle strength and mass. Note: These exercises are contraindicated while acute bleeding or edema is present.
Provide footboard, wrist splints, and trochanter or hand rolls, as appropriate.	Useful in maintaining functional position of extremities, hands, or feet and preventing complications such as contractures or footdrop.
Instruct in, and encourage use of, trapeze and "post position" for lower limb fractures.	Facilitates movement during hygiene, skin care, and linen changes; reduces discomfort of remaining flat in bed. "Post position" involves placing the uninjured foot flat on the bed with the knee bent while grasping the trapeze and lifting the body off the bed.
Assist with and encourage self-care activities such as bathing, shaving, and oral hygiene.	Improves muscle strength and circulation, enhances client control in situation, and promotes self-directed wellness.
Assist with mobility by means of wheelchair, walker, crutches, and/or canes as soon as possible. Instruct in safe use of mobility aids.	Early mobility reduces complications of bedrest, such as phlebitis, and promotes healing and normalization of organ function. Learning the correct way to use aids is important to maintain optimal mobility and client safety.
Monitor blood pressure (BP) with resumption of activity. Note reports of dizziness.	Postural hypotension is a common problem following prolonged bedrest and may require specific interventions, such as tilt table with gradual elevation to upright position.
Reposition periodically and encourage coughing and deep-breathing exercises.	Prevents or reduces incidence of skin and respiratory complications—decubitus ulcer, atelectasis, or pneumonia.
Auscultate bowel sounds. Monitor elimination habits and provide for regular bowel routine. Place on bedside commode, if feasible. Provide privacy.	Bedrest, use of analgesics, and changes in dietary habits can slow peristalsis and produce constipation. Nursing measures that facilitate elimination may prevent or limit complications.
Evaluate client's prior bowel habits.	Provides baseline for comparison with postsurgical concerns. The long-term use of opioids for pain and limited mobility causes constipation in orthopedic clients. Constipation is a major issue and needs immediate and ongoing attention.
Encourage increased fluid intake of 2000 to 3000 mL/d within cardiac tolerance, including acid-ash juices such as cranberry.	Keeps the body well hydrated, decreasing risk of urinary infection and stone formation, and helps to prevent constipation.
Provide diet high in proteins, carbohydrates, vitamins, and minerals, limiting protein content until after first bowel movement.	In the presence of musculoskeletal injuries, early good feeding is needed as nutrients required for healing are rapidly depleted. This can have a profound effect on muscle mass, tone, and strength. Note: Protein foods increase contents in small bowel, resulting in gas formation and constipation. Therefore, gastrointestinal (GI) function should be fully restored before protein foods are increased.
Increase the amount of roughage and fiber in the diet. Limit gas-forming foods.	Adding bulk to stool helps prevent constipation. Gas-forming foods may cause abdominal distention, especially in the presence of decreased intestinal motility.

(continues on page 714)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<b>Collaborative</b> Consult with physical or occupational therapist and/or rehabilitation specialist.	Useful in creating aggressive individualized activity or exercise program. Client may require long-term assistance with movement, strengthening, and weight-bearing activities as well as use of adjuncts, for example, walkers, crutches, canes; elevated toilet seats; pickup sticks or reachers; special eating utensils; and help for women with actions such as hooking a brassiere.
Refer to dietitian or nutrition team, as indicated.	The client with fractures, especially when associated with trauma, may have special nutritional considerations; for example, he or she may need enteral or parenteral feedings to maximize healing of tissues and bones.
Initiate bowel program—stool softeners, enemas, or laxatives, as indicated.	Important to promote regular bowel evacuation and prevent constipation.
Refer to psychiatric clinical nurse specialist or therapist, as indicated.	Client/SO may require more intensive treatment to deal with reality of current condition, prognosis, prolonged immobility, and perceived loss of control.

### NURSING DIAGNOSIS: risk for impaired Tissue Integrity/Pressure Ulcer

#### Possibly Evidenced By

Decrease in mobility; pressure over bony prominence  
Alteration in sensation, circulation  
Surface friction, shearing forces  
Incontinence

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Tissue Integrity: Skin & Mucous Membranes NOC

Verbalize relief of discomfort.  
Demonstrate behaviors or techniques to prevent skin breakdown and facilitate healing, as indicated.  
Achieve timely wound or lesion healing, if present.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Skin Surveillance NIC</b> <b>Independent</b> Examine the skin for open wounds, foreign bodies, rashes, bleeding, discoloration, duskiness, and/or blanching.	Provides information regarding skin circulation and problems that may be caused by application and/or restriction of cast, splint, or traction apparatus, or edema formation that may require further medical intervention.
Provide specialty beds and therapeutic foam mattress (e.g., Geomatts™) as indicated.	Used for clients with a high risk of skin breakdown or in whom long-term immobility is expected.
Massage skin and with emollient lotion. Keep bed linens dry and free of wrinkles. Place water pads or other padding under elbows and heels/float heels, as indicated.	Reduces pressure on susceptible areas and risk of abrasions or skin breakdown.
Reposition frequently. Encourage use of trapeze, if possible. Establish/adhere to regular turning schedule when client not able to turn independently.	Lessens constant pressure on same areas and minimizes risk of skin breakdown. Use of trapeze may reduce risk of abrasions to elbows and heels.
<b>Cast Care: Wet NIC</b> Plaster cast application and skin care: Cleanse skin with soap and water, rubbing gently with alcohol and/or dust with small amount of powder, per facility protocol.	Provides a dry, clean area for cast application.
Cut a length of stockinette to cover the area and extend several inches beyond the cast.	Useful for padding bony prominences, finishing cast edges, and protecting the skin.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Use palm of hand to apply, hold, or move cast and support on pillows after application; avoid using fingertips to hold cast.	Prevents indentations or flattening over bony prominences, such as back of heels, and weight-bearing areas, which would cause abrasions or tissue trauma. An improperly shaped or dried cast is irritating to the underlying skin and may lead to circulatory impairment. Fingertips may dent the cast when it is wet.
Trim excess plaster from edges of cast as soon as casting is completed.	Uneven plaster is irritating to the skin and may result in abrasions.
Promote cast drying by removing bed linen, exposing to circulating air.	Prevents skin breakdown caused by prolonged moisture trapped under cast.
Observe for potential pressure areas, especially at the edges of and under the splint/cast.	Pressure can cause ulcerations, necrosis, and/or nerve palsies. These problems may be painless when nerve damage is present.
Pad or petal tape the edges of the cast with waterproof tape or moleskin.	Provides an effective barrier to cast flaking and moisture. Helps prevent breakdown of cast material at edges and reduces skin irritation and excoriation.
Cleanse excess plaster from skin while still wet, if possible.	Dry plaster may flake into completed cast and cause skin irritation/damage.
Protect cast and skin in perineal area, providing frequent perineal care.	Prevents tissue breakdown and infection by fecal contamination.
Instruct client/SO to avoid inserting objects inside casts.	"Scratching an itch" may cause tissue injury.
Massage the skin around the cast edges with alcohol.	Has a drying effect, which toughens the skin. Creams and lotions are not recommended because excessive oils can seal cast perimeter, not allowing the cast to "breathe." Powders are not recommended because of potential for excessive accumulation inside the cast.

**Pressure Ulcer Prevention NIC****Collaborative**

Provide foam mattress, sheepskins, flotation pads, or air mattress, as indicated.

Because of immobilization of body parts, bony prominences other than those affected by the casting may suffer from decreased circulation.

Prepare for/assist with cast splitting (e.g., monovalve, bivalve), or cut a window in cast, as indicated.

Cutting or hinging the cast allows the release of pressure and provides access for wound and skin care.

**NURSING DIAGNOSIS: risk for Infection****Possibly Evidenced By**

Alteration in skin/tissue integrity, invasive procedures [skeletal traction]

Increased environmental exposure to pathogens

**Desired Outcomes/Evaluation Criteria—Client Will****Infection Severity NOC**

Achieve timely wound healing, be free of purulent drainage or erythema, and be afebrile.

**ACTIONS/INTERVENTIONS****RATIONALE****Infection Protection NIC****Independent**

Inspect the skin for preexisting irritation or breaks in continuity.

Pins or wires should not be inserted through skin infections, rashes, or abrasions—may lead to bone infection.

Assess pin sites and skin areas, noting reports of increased pain or burning sensation, or presence of edema, erythema, foul odor, or drainage.

May indicate onset of local infection or tissue necrosis, which can lead to osteomyelitis.

(continues on page 716)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Provide sterile pin and wound care according to protocol, and exercise meticulous handwashing.	May prevent cross-contamination and possibility of infection.
Instruct client not to touch the insertion sites.	Minimizes risk of contamination.
Line perineal cast edges with plastic wrap.	Damp, soiled casts can promote growth of bacteria.
Observe wounds for formation of bullae, crepitation, bronze discoloration of skin, and frothy or fruity-smelling drainage.	Signs suggestive of gas gangrene infection.
Assess muscle tone, reflexes, and ability to speak.	Muscle rigidity, tonic spasms of jaw muscles, and dysphagia reflect development of tetanus.
Monitor vital signs. Note presence of chills, fever, and malaise and any changes in mentation.	Hypotension and confusion may be seen with gas gangrene; tachycardia, chills, and fever reflect developing sepsis.
Investigate abrupt onset of pain or limitation of movement and localized inflammation, in injured extremity, along with fever, chills, fatigue, lethargy, or irritability.	May indicate development of osteomyelitis. Note: Post-traumatic osteomyelitis more commonly affects adults and typically occurs in the tibia. The major organism is <i>Staphylococcus aureus</i> . Infections with an open fracture often must be treated with a combination of antimicrobial agents and surgery (Kishner et al, 2016).
Institute prescribed isolation procedures.	Presence of purulent drainage requires wound and linen precautions to prevent cross-contamination.
<b>Collaborative</b>	
Monitor laboratory/diagnostic studies, for example:	
CBC	Anemia may be noted with osteomyelitis; leukocytosis is usually present with infective processes.
ESR, C-reactive protein (CRP)	Elevated in osteomyelitis.
Cultures and sensitivity of wound, serum, and/or bone	Identifies infective organism and effective antimicrobial agent(s).
MRI, CT scans	Detects abnormalities such as necrotic bone and soft tissue involvement indicative of osteomyelitis and is useful in gauging the success of therapy (Kishner et al, 2016).
Administer medications, as indicated, for example:	
IV/topical antibiotics	Broad-spectrum antibiotics may be used prophylactically or may be geared toward a specific microorganism.
Tetanus toxoid prophylaxis	May be given to client who is not current with immunization or who is at high risk because of wound type (e.g., puncture wounds, significant devitalized tissue, or contact with soil or manure likely to harbor tetanus organisms—outdoors, rural areas, or the work environment).
Provide wound or bone irrigations, and apply warm, moist soaks, as indicated.	Local debridement and cleansing of wounds reduce microorganisms and incidence of systemic infection. Continuous antimicrobial drip into bone may be necessary to treat osteomyelitis, especially if blood supply to bone is compromised.
Assist with procedures such as incision and drainage, placement of drains, and hyperbaric oxygen therapy.	Numerous procedures may be carried out in treatment of local infections, osteomyelitis, and gas gangrene.
Prepare for surgery, as indicated.	Sequestrectomy, removal of necrotic bone, is necessary to facilitate healing and prevent extension of infectious process.

**NURSING DIAGNOSIS:** **deficient Knowledge regarding condition, prognosis, treatment, self-care, and discharge needs**

**May Be Related To**

Insufficient information; insufficient knowledge of resources  
Misinformation presented by others

<b>NURSING DIAGNOSIS:</b> <b>deficient Knowledge regarding condition, prognosis, treatment, self-care, and discharge needs</b> (continued)	
<b>Possibly Evidenced By</b>	
Insufficient knowledge Inaccurate follow-through of instructions Development of preventable complications	
<b>Desired Outcomes/Evaluation Criteria—Client Will</b>	
<b>Knowledge: Treatment Regimen NOC</b>	
Verbalize understanding of condition, prognosis, and potential complications. Participate in learning process, and utilize available resources. Perform necessary procedures correctly and explain reasons for actions.	
<b>ACTIONS/INTERVENTIONS</b>	
<b>Teaching: Disease Process NIC</b>	
<i>Independent</i>	
Review pathology, prognosis, and future expectations.	Provides knowledge base from which client can make informed choices. Note: Internal fixation devices can ultimately compromise the bone's strength, and intra-medullary nails or rods and plates may be removed at a future date.
Provide accurate and relevant information regarding current and future needs.	Client can incorporate information into self-care plans, while minimizing difficulties associated with change.
<b>Cast care when client with new fracture is discharged to self-care</b>	
Discuss care of “green” or wet cast.	Promotes proper curing to prevent cast deformities and associated misalignment or skin irritation. Note: Placing a “cooling” cast directly on rubber or plastic pillows traps heat and increases drying time.
Suggest the use of a blow-dryer to dry small areas of dampened cast.	Cautious use can hasten drying.
Demonstrate use of plastic bags to cover plaster cast during wet weather or while bathing. Clean soiled cast with a slightly dampened cloth and some scouring powder.	Protects from moisture, which softens the plaster and weakens the cast. Note: Fiberglass casts are being used more frequently. They also need to be thoroughly dried if they get wet to avoid developing mold.
Recommend use of loose-fitting or adaptive clothing.	Facilitates dressing and grooming activities.
Suggest ways to cover toes if appropriate, for example, using stockinette or soft socks.	Helps maintain warmth and protect from injury.
List activities that the client can perform independently and those that require assistance.	Organizes activities around need and who is available to provide help.
Identify signs and symptoms requiring medical evaluation, for example, severe pain, fever or chills, or foul odors; changes in sensation, swelling, burning, numbness, tingling, skin discoloration, paralysis, or white/cool toes or fingertips; and warm spots, soft areas, or cracks in the cast.	Prompt intervention may reduce severity of complications such as infection or impaired circulation. Note: Some darkening of the skin reflecting vascular congestion may occur normally when walking on the casted extremity or using casted arm; however, this should resolve with rest and elevation.
Discuss post cast-removal instructions:	
Elevate the extremity, as needed.	Swelling and edema tend to recur briefly after cast removal.
Instruct client to continue activities and exercises as prescribed.	Reduces stiffness and improves strength and function of affected extremity.
Inform client that the skin under the cast is commonly mottled and covered with scales or crusts of dead skin.	It will be several weeks before normal appearance returns.
Instruct to wash skin gently with soap and water and lubricate with a protective emollient.	New skin is extremely tender because it has been protected beneath a cast.

(continues on page 718)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Inform client that muscles may appear flabby and atrophied (less muscle mass); recommend supporting the joint above and below the affected part and the use of mobility aids—elastic bandages, splints, braces, crutches, walkers, or canes.	Muscle strength will be reduced and new or different aches and pains may occur secondary to loss of support.
<b>For client discharged with external fixator</b>	
Review proper pin or wound care.	Reduces risk of bone and tissue trauma and infection, which can progress to osteomyelitis.
Emphasize the importance of not adjusting clamps or nuts of an external fixator device.	Tampering may alter compression and misalign fracture.
Recommend cleaning external fixator device regularly.	Keeping device free of contaminants reduces risk of infection.
<b>Miscellaneous interventions for optimal healing</b>	
Discuss dietary needs.	A balanced diet adequate in quality protein and rich in calcium promotes healing and general well-being.
Review individual drug regimen, as appropriate.	Proper use of pain medication and antiplatelet agents can reduce risk of complications.
Reinforce methods of mobility and ambulation aids/devices when indicated and any necessary support services (e.g., handicap transportation van for appointments).	Most fractures require casts, splints, or braces during the healing process, affecting client's mobility and independence. Further damage and delay in healing could occur secondary to failure to follow physician orders or improper use of ambulatory devices.
Identify available community services, such as a rehabilitation team, durable medical equipment providers, home nursing care or homemaker services, social services, vocational counselor.	Provides assistance to meet individual needs and support independence. Promotes optimal self-care and recovery.
Emphasize importance of clinical and therapy follow-up appointments.	Fracture healing may take as long as a year for completion, and client cooperation with the medical regimen facilitates proper union of bone. Physical therapy and occupational therapy may be indicated for exercises to maintain or strengthen muscles and improve function.
Discuss plan for future prophylactic antibiotic use.	When hardware, such as pins, screws, and plates, is implanted, it provides a place for infection to develop. If there are procedures that open the GI tract to the bloodstream, such as dental procedures or a colonoscopy, antibiotics should be given.

#### POTENTIAL CONSIDERATIONS following acute hospitalization (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

##### In addition to surgical considerations:

- **risk for Trauma**—balancing difficulties, weakness, reduced muscle coordination, history of previous trauma
- **impaired physical Mobility**—neuromuscular skeletal impairment, pain/discomfort, prescribed movement restrictions (limb immobilization)
- **Self-Care deficit**—musculoskeletal impairment, decreased strength/endurance, pain
- **risk for Infection**—inadequate primary defenses: broken skin, traumatized tissues, environmental exposure, invasive procedures, skeletal traction

## AMPUTATION

I. **Pathophysiology**—partial or complete detachment of body part with residual extremity covered with well-vascularized muscle and skin, although reattachment surgery may be possible for fingers, hands, and arms

- a. Primarily two types of amputations
  - i. Open or provisional: requires subsequent revisions
  - ii. Closed or flap: All surgical revision is performed and the wound closed in one procedure.

- b. Amputation levels (Kalapatapu, 2017): the level of the amputation is dictated by the extent of the disease, healing potential of the stump, and rehabilitation potential of the client. Although preservation of limb length is desirable, removal of all nonviable and infected tissue is a higher priority.
  - i. Lower-extremity amputation: partial foot or toe, below knee (BKA), above knee (AKA), hip disarticulation or hemipelvectomy, and bilateral lower-limb loss. A variety of foot amputations are available that can salvage the client's ability to ambulate with orthotic modifications, including mid- and hindfoot amputation, transmetatarsal amputation, and digit amputation.
  - ii. Upper-extremity amputation: partial hand or finger, below elbow, above elbow, shoulder disarticulation or forequarter, and bilateral upper-limb loss
  - c. Two basic types of prosthetic designs are used: exoskeletal and endoskeletal (see Glossary).

## II. Etiology

- a. Varied causes (Ertl et al, 2016; Kalapatapu, 2017; Kishner & Laborde, 2015)
  - i. Unsalvageable extremity due to critical limb ischemia in person with vascular disease. Main causes are vascular disease (54%) (including diabetes and peripheral arterial disease), trauma (45%), and cancer (less than 2%) (Ziegler-Graham et al, 2008).
  - ii. Trauma resulting in mangled extremity or failed attempt at limb salvage. Examples include direct limb transection or a severe open fracture with an associated unreconstructable neurovascular injury (often associated with motor vehicle crashes or industrial accidents),

- battlefield wounds. *Note:* Between 2001 and 2016, about 1650 U.S. troops lost hands, arms, legs, or feet in current combat locales (Montgomery, 2017).
- iii. Malignant bone tumors
- iv. Infections with extensive soft tissue or bony destruction, such as osteomyelitis, gangrene
- v. Congenital disorders: approximately 5% of cases
- b. Lower-extremity amputations are performed much more frequently than upper-extremity amputations.
- c. Upper-extremity amputations generally result from trauma caused by industrial accidents.

## III. Statistics

- a. Morbidity: In 2017, nearly 2 million persons were living with the loss of a limb with numbers of new amputations (includes all types) widely ranging from 30,000 to 70,000 in the United States each year (Ertl et al, 2016; Kishner & Laborde, 2015; Statistics Brain, 2016). Retrospective studies have shown that the rate of leg and foot amputations among U.S. adults 40 years or older with diagnosed diabetes declined by 65% between 1996 and 2008 (Li et al, 2012; Salcido, 2015).
- b. Mortality: The most common causes of death following amputation for peripheral artery disease (PAD) are cardiac complications, sepsis, and pneumonia (Kalapatapu, 2017). In 2013, among 186,338 older people with identified PAD who underwent major lower-extremity (LE) amputation, the mortality rate was 13.5% at 30 days, 48.3% at 1 year, and 70.9% at 3 years (Jones et al, 2013).
- c. Costs: Hospital costs associated with amputation totaled more than \$8.3 billion based on 2009 data (Amputee Coalition, 2017).

## GLOSSARY

**Complete amputation:** Total detachment of appendage or limb from the body.

**Endoskeletal prosthetic:** Aluminum, titanium, and other tubular materials form the inner structure, providing strength; external shape is removable, usually composed of foam or skin-simulating material.

**Exoskeletal prosthetic:** Outer plastic laminated skin with wood or urethane foam interiors where the strength is provided by the outer layer.

**Neuromas:** Painful proliferation of nerve fibers at the proximal end of a severed nerve.

**Partial amputation:** Some soft tissue remains attached to the body.

**Prosthetic:** An artificial substitute or replacement of a part of the body, such as a tooth, heart valve, a joint (e.g., hip, a knee), or a limb—the leg, arm, which is designed for functional and/or cosmetic reasons.

**Residual limb:** Remaining portion of the amputated limb (once referred to as the stump).

## CARE SETTING

Client is treated in inpatient acute surgical unit and subacute or rehabilitation unit.

## RELATED CONCERNS

Cancer, general considerations, page 945

Diabetes mellitus and diabetic ketoacidosis, page 454

Psychosocial aspects of care, page 835

Surgical intervention, page 873

## CLIENT ASSESSMENT DATABASE

Data depend on underlying reason for surgical procedure, for example, severe trauma, peripheral vascular/arterial occlusive disease, diabetic neuropathy, osteomyelitis, and cancer.

DIAGNOSTIC DIVISION MAY REPORT	MAY EXHIBIT
<b>ACTIVITY/REST</b> <ul style="list-style-type: none"><li>• Actual or anticipated limitations imposed by condition or amputation</li></ul>	
<b>CIRCULATION</b>	<ul style="list-style-type: none"><li>• Presence of edema</li><li>• Absent or diminished pulses in affected limb or digits</li></ul>
<b>EGO INTEGRITY</b> <ul style="list-style-type: none"><li>• Concern about negative effects or anticipated changes in lifestyle, financial situation, reactions of others</li><li>• Feelings of helplessness, powerlessness</li></ul>	<ul style="list-style-type: none"><li>• Anxiety, apprehension</li><li>• Irritability</li><li>• Anger, frustration</li><li>• False cheerfulness</li><li>• Withdrawal, grief</li></ul>
<b>NEUROSENSORY</b> <ul style="list-style-type: none"><li>• Loss of sensation in affected area</li><li>• Phantom pain</li></ul>	
<b>SAFETY</b> <ul style="list-style-type: none"><li>• Loss of ability to walk; altered gait</li><li>• History of falls, traumatic injuries, risky behavior, or work environment resulting in injury</li></ul>	<ul style="list-style-type: none"><li>• Necrotic or gangrenous area</li><li>• Nonhealing wound</li><li>• Local infection</li><li>• Altered gait; increased risk for falls</li></ul>
<b>SEXUALITY</b> <ul style="list-style-type: none"><li>• Concern about intimate relationships</li></ul>	
<b>SOCIAL INTERACTION</b> <ul style="list-style-type: none"><li>• Problems related to illness or condition</li><li>• Concern about role function</li><li>• Concern about reaction of others</li></ul>	
<b>TEACHING/LEARNING</b>	
<b>DISCHARGE PLAN CONSIDERATIONS</b> <ul style="list-style-type: none"><li>• May require assistance with wound care and supplies, adaptation to prosthesis or other ambulatory devices, transportation, homemaker or maintenance tasks, and possibly self-care activities and vocational retraining</li></ul>	
► Refer to section at end of plan for postdischarge considerations.	

## DIAGNOSTIC STUDIES

Studies depend on the underlying condition necessitating amputation and are used to determine the appropriate level for amputation.

TEST WHY IT IS DONE	WHAT IT TELLS ME
• <b>X-rays:</b> Used to visualize pathology and the extent of involvement.	Identify skeletal abnormalities, trauma, or mass or tumor.
• <b>Computed tomography (CT) scan:</b> Used to visualize changes of structure within the body and bone alignment.	Identifies soft tissue and bone destruction, neoplastic lesions, osteomyelitis, and hematoma formation.
• <b>Angiography and blood flow studies:</b> Evaluates circulation and tissue perfusion.	Helps predict potential for tissue healing after amputation.
• <b>Doppler ultrasound, laser Doppler flowmetry:</b> Performed to assess and measure blood flow.	Determines adequacy of skin microcirculation and helps predict tissue or muscle viability and primary wound healing.
• <b>Transcutaneous oxygen pressure:</b> Maps out areas of greater and lesser perfusion in the involved extremity.	Helps determine lowest level at which to perform amputation for maximum preservation of limb length and successful healing.
• <b>Thermography:</b> Measures temperature differences in an ischemic limb at two sites—the skin and the center of the bone.	The lower the difference is between the two readings, the greater the chances will be for healing.
• <b>C-reactive protein (CRP):</b> Inflammatory marker as indicator of infection.	Important if osteomyelitis or sepsis is suspected or known factor in considering amputation. A level greater than 8 mg/L indicates significant infection.
• <b>White blood cell (WBC) count/differential:</b> Assesses body's ability to respond to and eliminate infection.	Elevation and "shift to left" suggest infectious process.
• <b>Biopsy:</b> Determines presence of pathology and treatment needs or options.	Confirms diagnosis of benign or malignant mass.

## NURSING PRIORITIES

1. Alleviate pain.
2. Prevent complications.
3. Promote mobility and functional abilities.
4. Support psychological and physiological adjustment.
5. Provide information about surgical procedure, prognosis, and treatment needs.

## DISCHARGE GOALS

1. Pain relieved or controlled.
2. Complications prevented or minimized.
3. Mobility and function regained or compensated for.
4. Dealing with current situation realistically.
5. Surgical procedure, prognosis, and therapeutic regimen understood.
6. Plan in place to meet needs after discharge.

### NURSING DIAGNOSIS: acute Pain

#### May Be Related To

Physical injury agent (e.g., tissue and nerve trauma)  
[Psychological (e.g., impact of loss of body part, stress, anxiety)]

#### Possibly Evidenced By

Self-report of intensity and characteristics of pain using standardized scale/instrument  
Guarding/protective behavior  
Narrowed focus  
Changes in vital signs

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Pain Level NOC

Report pain is relieved or controlled.  
Appear relaxed and able to rest and sleep appropriately.  
Verbalize understanding of phantom pain and methods to provide relief.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Pain Management: Acute NIC</b> <i>Independent</i>	
Document location and intensity of pain (0 to 10, or similar coded scale) as well as quality and aggravating factors. Investigate changes in pain characteristics—numbness and tingling.	Aids in evaluating need for and effectiveness of interventions. Changes may indicate developing complications, such as necrosis or infection.
Elevate affected part by raising foot of bed slightly or using a pillow or sling for upper-limb amputation.	Lessens edema formation by enhancing venous return; reduces muscle fatigue and skin or tissue pressure. Note: After initial 24 hours and in absence of edema, residual limb may be extended and kept flat.
Provide or promote general comfort measures (e.g., frequent turning, back rub) and diversional activities. Encourage use of stress management techniques, such as deep-breathing exercises, visualization and guided imagery, and Therapeutic Touch.	Nonpharmacological measures can refocus attention, promote relaxation, may enhance coping abilities, and may decrease occurrence of phantom-limb pain.
Investigate reports of progressive or poorly localized pain unrelieved by analgesics.	May indicate developing compartment syndrome, especially following traumatic injury. (Refer to CP: Fractures; ND: risk for peripheral Neurovascular Dysfunction.)
Acknowledge reality of residual limb pain and phantom pain and that various modalities will be tried for pain relief.	Residual limb pain (RLP, also known as stump pain) is believed to come from injuries to bone, muscle, nerve, and skin at the amputation site (Ertl et al, 2016; Hsu & Cohen, 2013). Stump pain is typically described as a sharp, burning, electrical-like, or "skin-sensitive" pain localized to a superficial incision, or be perceived deep in the residual limb, or can sometimes encompass the whole residual limb. Similar to phantom pain, stump pain can persist for years (Ehde et al, 2000). In contrast, phantom limb pain (PLP) is thought to originate in the part of the brain that controlled the limb before it was amputated. PLP is a painful or unpleasant sensation in the distribution of the lost body part and may be due to complete or partial interruption of afferent nerve impulses. PLP varies in character from sharp, shooting, or electrical-like to dull, squeezing, and cramping. It can be localized to the entire limb or just one region of the missing limb. PLP typically occurs within the first 6 months after loss of a limb, but it can persist for years (Hsu & Cohen, 2013).
<b>Collaborative</b>	
Administer medications, as indicated, such as the following:	Treatment of postamputation pain (PAP) involves a multimodal approach that includes injections, pharmacotherapy, complementary and alternative therapies, surgery, and prevention.
Opioid analgesics, for example, morphine sulfate (Astramorph, MS Contin), fentanyl patch; combination agents: oxycodone with acetaminophen (Percocet); injected/infused NMDA antagonists (e.g., ketamine [Ketalar], memantine [Namenda]; calcitonin [Miacalcin]); anti-depressants (e.g., amitriptyline [Elavil], nortriptyline [Pamelor]); anticonvulsants (e.g., gabapentin [Neurontin], pregabalin [Lyrica]); and anti-inflammatory agents (e.g., ibuprofen [Motrin])	Many medications and routes of administration may be used. In acute PAP, opioid analgesics are the mainstay of pain management to reduce pain and muscle spasm. When first- and second-line drugs (e.g., opioids, anticonvulsants, or antidepressants) fail to provide satisfactory analgesia, third-line drugs such as ketamine and calcitonin may provide a suitable option. However, all of these drugs have shown mixed results in relieving RLP or PLP pain in studies (Amputee Coalition of America & U.S. Army Amputee Patient Care Program, 2014; Fudin, 2009; Hickman, 2013). Note: Some studies have shown that botulinum toxin resulted in a statistically significant improvement in RLP at 1 month and was sustained over the 6-month study period (Wu et al, 2012).
Instruct in, and monitor use of, patient-controlled analgesia (PCA).	PCA provides for continuous and timely drug administration, preventing fluctuations in pain level and muscle tension and spasms associated with surgical procedures.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Refer to interdisciplinary providers as appropriate—pain management specialist, physical therapist, prosthetist, orthopedic surgeon, and neurosurgeon.	A multidisciplinary approach is required, and many therapy modalities may be needed both in the acute and the long-term management of pain.
Discuss and monitor use of transcutaneous electrical nerve stimulation (TENS) of the residual limb.	TENS may help to treat phantom limb pain in some people, especially in combination with medications for neuropathic pain.

### NURSING DIAGNOSIS: risk for ineffective peripheral Tissue Perfusion

#### Possibly Evidenced By

Diabetes mellitus; trauma [peripheral vascular disease; hypovolemia; tissue edema/hematoma formation]

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Tissue Perfusion: Peripheral NOC

Maintain adequate tissue perfusion as evidenced by palpable peripheral pulses; warm, dry skin; and timely wound healing.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Circulatory Precautions NIC</b>	
<b>Independent</b>	
Monitor vital signs. Palpate peripheral pulses, noting strength and equality.	General indicators of circulatory status and adequacy of perfusion.
Perform periodic neurovascular assessments—sensation, movement, pulse, skin color, and temperature.	Amputation wound healing is a concern because most are performed for compromised circulation, for example, with peripheral vascular disease (PWD) or damaged soft tissue resulting from trauma (Ertl et al, 2016). Postoperative tissue edema, hematoma formation, or restrictive dressings may impair circulation to residual limb, resulting in tissue necrosis.
Note type of dressing used—soft, soft with pressure wrap, semirigid, graduated pressure stump shrinker.	Postoperative dressing varies, each with its advantages and disadvantages. For example, a soft dressing does not control edema and may not shape stump well to prepare for prosthesis. Adding a pressure wrap distributes pressure but requires measures to avoid possible circulatory impairment and contracture. Semirigid dressings (e.g., plaster splint, Unna paste bandage) or rigid dressings allow for decreased edema and immediate postoperative prosthesis with early ambulation but limit access to the wound (Virani et al, 2015).
Inspect dressings and drainage device, noting amount and characteristics of drainage, especially in client receiving antithrombotic therapy, including DVT prophylaxis.	Continued blood loss may indicate need for additional fluid replacement and evaluation for coagulation defect or surgical intervention to ligate bleeder, hematoma evacuation, or revision of stump.
Support residual limb at all times, and avoid placing limb in dependent position when client is seated. Encourage and assist with early ambulation.	Prevents dependent edema formation and associated circulatory stasis with its potential local and systemic complications.
Investigate reports of persistent or unusual pain in operative site.	Hematoma can form in muscle pocket under the flap, compromising circulation and intensifying pain.
Evaluate nonoperated lower limb and residual limb for redness, tenderness, or stump hematoma.	There is an increased incidence of thrombus formation in amputee with preexisting peripheral vascular disease or diabetic changes. However, it also appears that deep vein thrombosis (DVT) is associated with traumatic amputations. For example, a recent study found a 59% incidence of DVT in clients with combat-related injuries requiring major amputation (Hannon et al, 2016).

(continues on page 724)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<b>Collaborative</b>	
Administer intravenous (IV) fluids and blood products as indicated.	Maintains circulating volume to maximize tissue perfusion.
Apply antiembolic or sequential compression hose to nonoperated leg, as appropriate.	Enhances venous return, reducing venous pooling and risk of thrombophlebitis.
Administer anticoagulant(s), as indicated.	May be useful in preventing thrombus formation without increasing risk of postoperative bleeding or hematoma formation.
Monitor laboratory studies, for example:	
Hemoglobin/hematocrit (Hgb/Hct)	Indicators of hypovolemia, or dehydration, which can impair tissue perfusion.
Prothrombin time (PT)/activated partial thromboplastin time (aPTT)	Evaluates need for, and effectiveness of, anticoagulant therapy and identifies developing complications.

## NURSING DIAGNOSIS: risk for Infection

### Possibly Evidenced By

Alteration in skin integrity, traumatized tissue; invasive procedures; malnutrition  
Chronic illness (e.g., diabetes mellitus, PAD, malignancy)

### Desired Outcomes/Evaluation Criteria—Client Will

#### Wound Healing: Primary Intention NOC

Achieve timely wound healing, be free of purulent drainage or erythema, and be afebrile.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Wound Care NIC</b>	
<b>Independent</b>	
Evaluate client's risk for infection.	The client's risk is closely associated with preoperative conditions. For example, amputation may have been performed because of prior infection (e.g., associated with diabetes, pressure, or traumatic injuries). Other risk factors include client's age and general health, environmental conditions, and lifestyle issues (e.g., smoking, drug use). However, postoperatively the client remains at high risk for new or recurrent infections, which can impede stump (and other) tissue healing and impact quality of life. Note: Wound infection rates widely, but a range of 13% to 40% (following major lower extremity amputation) was reported in one study. This is most likely because lower-extremity amputation is often associated with open, infected wounds classified as contaminated at the time of surgery (Kalapatapu, 2017).
Maintain strict hand hygiene measures, using soap and water or antibacterial soaps, before and after client care and after glove removal.	Hand hygiene remains the cornerstone of infection prevention and control in healthcare and community settings.
Maintain aseptic technique when changing dressings and caring for wound.	Minimizes opportunity for introduction of bacteria.
Inspect wound (noting redness and excess warmth) and dressings daily or per prescription; note characteristics of drainage, particularly in client with unexplained fever or reporting excessive stump pain.	Early detection of developing infection provides opportunity for timely intervention and prevention of more serious complications such as osteomyelitis.
Maintain patency and routinely empty drainage device.	Hemovac and Jackson-Pratt drains facilitate removal of drainage, promoting wound healing and reducing risk of infection.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Cover dressing with plastic when using the bedpan if incontinent.	Reduces risk of contamination in high-level, lower-limb amputation.
Expose residual limb to air and wash with mild soap and water after dressings are discontinued.	Maintains cleanliness, minimizes skin contaminants, and promotes healing of tender, fragile skin.
Monitor vital signs.	Temperature elevation and tachycardia may reflect developing sepsis.
<b>Collaborative</b>	
Obtain wound and drainage cultures and sensitivities, as appropriate.	Identifies presence of infection, specific organisms, and appropriate therapy.
Administer antibiotics, as indicated.	Wide-spectrum antibiotics may be used prophylactically, or antibiotic therapy may be geared toward specific organisms.
Monitor serum glucose levels, administer antidiabetic medications as appropriate.	Hyperglycemia can promote growth of bacteria and delay healing.

## NURSING DIAGNOSIS: impaired physical Mobility

### May Be Related To

Alteration in bone structure integrity; neuromuscular, musculoskeletal or sensory-perceptual impairment (e.g., loss of a limb—particularly a lower extremity)  
Decrease in muscle strength, mass; physical deconditioning; prescribed movement restrictions  
Pain, pharmaceutical agent  
Insufficient knowledge of mobility strategies; insufficient environmental support

### Possibly Evidenced By

Limited range of motion; difficulty turning; slowed/uncoordinated movement  
Postural instability; alteration in gait  
Discomfort

### Desired Outcomes/Evaluation Criteria—Client Will

#### Coordinated Movement NOC

Increase strength and function of affected and compensatory body parts.  
Move about environment safely.

#### Knowledge: Body Mechanics NOC

Verbalize understanding of individual situation and safety measures.  
Demonstrate techniques and behaviors that enable resumption of activities.  
Maintain position of function as evidenced by absence of contractures.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Amputation Care NIC</b>	
<b>Independent</b>	
Provide residual limb care on a routine basis; for example, inspect the area, clean and dry it thoroughly, and rewrap the residual limb with elastic bandage or air splint. Conversely, apply a “stump shrinker” or heavy stockinette sock for “delayed” prosthesis.	Provides opportunity to evaluate healing and note complications unless covered by immediate prosthesis. Wrapping residual limb controls edema and helps form residual limb into conical shape to facilitate fitting of prosthesis. Note: Air splint may be preferred because it permits visual inspection of the wound.
Measure circumference periodically.	Measurement is done to estimate shrinkage to ensure proper fit of sock and prosthesis.
Rewrap residual limb immediately with an elastic bandage; elevate if “immediate or early” cast is accidentally dislodged. Prepare for reapplication of cast.	Edema will occur rapidly, thus delaying rehabilitation.
Assist with specified range-of-motion (ROM) exercises for both the affected and unaffected limbs, beginning early in postoperative stage.	Prevents contracture deformities, which can develop rapidly and could delay prosthesis usage.

(continues on page 726)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Encourage active and isometric exercises for upper torso and unaffected limbs.	Increases muscle strength to facilitate transfers and ambulation and promotes mobility and more normal lifestyle.
Provide trochanter rolls, as indicated.	Prevents external rotation of lower-limb residual limb.
Instruct client to lie in prone position, as tolerated, at least twice a day with pillow under abdomen and lower-extremity residual limb.	Strengthens extensor muscles and prevents flexion contracture of the hip, which can begin to develop within 24 hours of sustained malpositioning.
Caution against keeping pillow under lower-extremity residual limb or allowing BKA limb to hang dependently over side of bed or chair.	Use of pillows can cause permanent flexion contracture of hip; a dependent position of residual limb impairs venous return and may increase edema formation.
Demonstrate/assist with transfer techniques and use of mobility aids such as a trapeze, crutches, or a walker.	Facilitates self-care and client's independence. Proper transfer techniques prevent shearing abrasions/dermal injury related to "scooting."
Assist with ambulation with timing based on client's specific needs and prosthesis implemented:	Today, prosthetics are available for almost every body part and for just about every condition. Timing is completely individual. Note: Current researchers are working out how to best match prosthetic components with the needs of amputees and investigating different care strategies for residual limbs after surgery. These strategies may improve understanding of wound care in general and could ultimately reduce the need for amputations. Already, wound healing that used to take weeks or even months can now occur much faster (VA Research and Development Program, n.d.).
Immediate postoperative fitting	Reduces potential for injury. Ambulation after lower-limb amputation depends on timing of prosthesis placement.
Early postoperative fitting	A rigid dressing is applied to the residual limb and a pylon and artificial foot are attached. Weight-bearing begins within 24 to 48 hours. Weight-bearing normally does not occur until 10 to 30 days postoperatively.
Delayed fitting	More common in areas that do not have facilities available for immediate or early application of prosthesis or when the condition of the residual limb and/or client precludes these choices.
Help client continue preoperative muscle exercises as able or when allowed out of bed; for example, the client should perform abdomen-tightening exercises and knee bends, hop on foot, and stand on toes while holding on to chair for balance.	Contributes to gaining improved sense of balance and strengthens compensatory body parts.
Instruct client in residual limb-conditioning exercises, for example, pushing the residual limb against a pillow initially, then progressing to harder surface.	Hardens the residual limb by toughening the skin and altering feedback of resected nerves to facilitate use of prosthesis.
<b>Collaborative</b> Refer to rehabilitation team, for example, physical and occupational therapy and prosthetic specialists.	Provides for creation of exercise and activity program to meet individual needs and strengths and identifies mobility functional aids to promote independence. Early use of a temporary prosthesis promotes activity and enhances general well-being and a positive outlook. Note: Vocational counseling and/or retraining also may be indicated.
Provide foam or flotation mattress.	Reduces pressure on skin and tissues that can impair circulation, potentiating risk of tissue ischemia and breakdown.

## NURSING DIAGNOSIS: Grieving

### May Be Related To

Loss of significant object (e.g., body part, change in functional abilities, professional/family role, perception of self)

**NURSING DIAGNOSIS:** **Grieving** (continued)**Possibly Evidenced By**

Anger; psychological distress; detachment  
Finding meaning in a loss; personal growth

**Desired Outcomes/Evaluation Criteria—Client Will****Grief Resolution NOC**

Begin to show adaptation and verbalize acceptance of self in situation (amputee).  
Recognize and incorporate changes into self-concept in accurate manner without negating self-esteem.  
Develop realistic plans for adapting to new role or role modifications.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Grief Work Facilitation NIC</b>	
<b>Independent</b>	
Assess and consider client's preparation for and view of amputation.	Research shows that amputation poses serious threats to client's psychological and psychosocial adjustment. Client who views amputation as life-saving or reconstructive may be able to more quickly accept the new self. Client with sudden traumatic amputation or who considers amputation to be the result of failure in other treatments is at greater risk for disturbances in self-concept and complicated grieving.
Encourage expression of fears, negative feelings, and grief over loss of body part.	Venting emotions helps client begin to deal with the fact and reality of life without a limb.
Reinforce preoperative information, including type and location of amputation, type of prosthetic fitting if appropriate (i.e., immediate, delayed), and expected postoperative course, including pain control and rehabilitation.	Provides opportunity for client to question and assimilate information and begin to deal with changes in body image and function, which can facilitate postoperative recovery.
Assess degree of support available to client.	Sufficient support by significant other (SO) and friends can facilitate rehabilitation process and grief resolution.
Discuss client's perceptions of self, related to change, and how client sees self in usual lifestyle and role functioning.	Aids in defining concerns in relation to previous lifestyle and facilitates problem-solving. For example, client likely fears loss of independence, ability to work or express sexuality, and may experience role and/or relationship changes.
Ascertain individual strengths and identify previous positive coping behaviors.	Helpful to build on strengths that are already available for client to use in dealing with current situation.
Encourage participation in activities of daily living (ADLs). Provide opportunities to view and care for residual limb, using the moment to point out positive signs of healing.	Promotes independence and enhances feelings of self-worth. Although integration of residual limb into body image can take months or even years, looking at the residual limb and hearing positive comments made in a normal, matter-of-fact manner can help client with this acceptance.
Encourage or provide for a visit by another amputee, especially one who is successfully rehabilitating.	A peer who has been through a similar experience serves as a role model and can provide validity to comments and hope for recovery and a positive future.
Provide open environment for client to discuss concerns about sexuality.	Promotes sharing of beliefs and values about sensitive subject and identifies misconceptions or myths that may interfere with adjustment to situation.
Note withdrawn behavior, negative self-talk, use of denial, depression, or overconcern with actual or perceived changes.	Identifies stage of grief and may indicate need for more intensive interventions. Note: Studies show that posttraumatic stress disorder (PTSD) develops in 20% to 22% of people who have amputations associated with combat or accidental injury (Kalapatapu, 2017).
<b>Collaborative</b>	
Discuss availability of various resources, for example, psychiatric or sexual counseling, a prosthetist, or a physical or occupational therapist.	May need assistance and long-term support to facilitate optimal adaptation and establish a "new" normal for future.

**NURSING DIAGNOSIS:** **deficient Knowledge regarding condition, prognosis, treatment, self-care, and discharge needs****May Be Related To**

Insufficient information/knowledge of resources, or interest in learning  
Misinformation presented by others

**Possibly Evidenced By**

Insufficient knowledge  
Inaccurate follow-through of instructions  
Development of preventable complications

**Desired Outcomes/Evaluation Criteria—Client Will****Knowledge: Disease Process NOC**

Verbalize understanding of condition, disease process, and potential complications.

**Knowledge: Treatment Regimen NOC**

Verbalize understanding of therapeutic needs.  
Correctly perform necessary procedures and explain reasons for the actions.  
Initiate necessary lifestyle changes and participate in treatment regimen.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Amputation Care NIC</b> <i>Independent</i> Review disease process, surgical procedure, and future expectations.	Provides knowledge base from which client can make informed choices.
Instruct in dressing and wound care, inspection of residual limb using mirror to visualize all areas, skin massage, and appropriate wrapping of the residual limb.	Promotes competent self-care, facilitates healing and fitting of prosthesis, and reduces potential for complications.
Discuss general residual limb care, for example:  Wash daily with mild soap and water; rinse and pat dry. Do this daily or more often if client sweats a lot or is treating a rash or infection.	Hygiene of residual limb is critical because most of the time it is enclosed in the socket or liner of the prosthesis, rendering it more prone to skin breakdown and infection.
Massage the residual limb after dressings are discontinued and suture line is healed.	Massage softens the scar and prevents adherence to the bone, decreases tenderness, and stimulates circulation.
Avoid the use of alcohol-based lotions or use of powders.	Although a small amount of lotion may be indicated if skin is dry, emollients and creams soften skin and may cause maceration when prosthesis is worn. Powder may cake, potentiating skin irritation.
Wear only properly fitted, clean, wrinkle-free limb sock.	Residual limb may continue to shrink for up to 2 years, and an improperly fitting sock or one that is mended or dirty can cause skin irritation or breakdown.
Use clean cotton T-shirt under harness for upper-limb prosthesis.	Absorbs perspiration; prevents skin irritation from harness.
Review common problems and appropriate actions.	Problems can occur even when client is taking precautions, for example, the development of a red, sore area that does not resolve when prosthesis is off or a blister caused by pressure between socket liner and skin. These problems need early medical follow-up if home interventions are not effective.
Emphasize importance of well-balanced diet and adequate fluid intake.	Provides needed nutrients for tissue regeneration and healing, aids in maintaining circulating volume and normal organ function, and aids in maintenance of proper weight. Note: Weight changes affect fit of prosthesis.
Recommend cessation of smoking. Offer referral resources for cessation programs.	Smoking potentiates peripheral vasoconstriction, impairing circulation and tissue oxygenation.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Review and demonstrate care of prosthetic device. Stress importance of routine maintenance and periodic refitting.	Ensures proper fit and alignment, reduces risk of complications, and prolongs life of prosthesis.
Encourage continuation of postoperative exercise program.	Enhances circulation, healing, and function of affected part, facilitating adaptation to prosthetic device.
Identify techniques to manage phantom sensation and phantom pain. (Refer to ND: acute Pain.)	Persistent and/or recurring pain requires long-term management, with multiple strategies and modalities, including desensitization therapy, intermittent compression, medications, TENS, and nerve blocks. Note: Electrical stimulation offers a short-term rerouting or stimulation of different nerve pathways, thus reducing the activity of the usual pain patterns.
Encourage taking care of whole self: body, mind, and spirit. Emphasize socialization, stress management, relaxation training, or counseling.	Various techniques may be implemented, such as relaxation breathing, exercises, visualization, or biofeedback to reduce muscle tension and enhance client's control of situation and coping abilities.
Identify signs and symptoms requiring medical evaluation—edema, erythema, increased or odorous drainage from incision, changes in sensation, movement, skin color, and persistent phantom pain.	Prompt intervention may prevent serious complications and/or loss of function. Note: Chronic phantom limb pain may indicate neuroma, requiring surgical resection.
Identify community and rehabilitation support, such as a certified prosthetist-orthotist, amputee groups, home-care and homemaker services, as needed.	Facilitates transfer to home, supports independence, and enhances coping.

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

**In addition to considerations in surgical intervention plan of care:**

- **impaired physical Mobility**—decreased muscle mass/strength; musculoskeletal impairment; deconditioning; decreased endurance
- **risk for physical Trauma**—balancing difficulties, muscle weakness, reduced muscle coordination, lack of safety precautions, hazards associated with use of assistive devices
- **disturbed Body Image**—loss of body part, change in functional abilities
- **Self-Care deficit/impaired Home Maintenance (dependent on location of amputation)**—musculoskeletal impairment, decreased strength/endurance, pain, depression

## TOTAL JOINT REPLACEMENT

### I. Purpose

- a. Definitive treatment for advanced, irreversibly damaged joints with loss of function and unremitting pain
- b. Common conditions: degenerative osteoarthritis (OA) and rheumatoid arthritis (RA); selected fractures, such as with hip and femoral neck; joint instability; congenital hip disorders; avascular necrosis

### II. Procedures

- a. Performed on any joint except the spine, with hip and knee replacements the most common procedures
- b. Prosthesis may be metallic, polyethylene, ceramic, or a combination
- c. Implanted with methylmethacrylate cement or may be a porous, coated implant that encourages bony ingrowth

### III. Statistics

- a. Morbidity: The 2016 report from the American Joint Replacement Registry (AJRR) shows a total of 161,040

procedures for 2015 (AJRR, 2016). According to a study published in 2014, 4.7 million had undergone total knee replacement, and 2.5 million total hip replacement (Mayo Clinic Staff, 2014).

- b. Mortality: Rate is low. Studies reviewed by Bone and Joint Research and published by the National Center for Biotechnical Information (NCBI, National Institutes of Health [NIH], 2014) suggest that total hip replacement may cause a short-term increased risk of mortality—0.30% at 30 days and 0.65% at 90 days (NCBI, NIH, 2014).
- c. Cost: A recent study of **average hospital costs** for a typical total knee arthroplasty (TKA) in the United States was \$31,124, and the average price of a total hip arthroplasty (THA) was \$30,124, although wide variations occurred across geographic regions (Blue Cross Blue Shield Blue Health Intelligence, 2015).

## G L O S S A R Y

**Arthroplasty:** Reconstruction or replacement of a diseased or damaged joint.

**Cemented joint replacement (cemented joint arthroplasty):** Procedure in which bone cement or polymethylmethacrylate (PMMA) is used to fix the prosthesis in place in the joint.

**Hemiarthroplasty:** Replacement of only the femoral head.

**Ingrowth, or cementless, joint replacement (ingrowth, or cementless, arthroplasty):** Procedure that does not involve bone cement to fix the prosthesis in place; an

anatomic or press fit with bone ingrowth into the surface of the prosthesis leads to a stable fixation.

**Primary joint replacement:** Initial surgical procedure.

**Revision:** Second or succeeding procedures to correct loose, unstable hardware or address return of pain in the joint.

**THA:** Total hip arthroplasty, also called total hip replacement (THR).

**TJR:** Total joint replacement.

**TKA:** Total knee arthroplasty, also called total knee replacement (TKR).

## CARE SETTING

Client is treated in an inpatient acute surgical unit and subacute or rehabilitation unit.

## RELATED CONCERNS

## CLIENT ASSESSMENT DATABASE

### DIAGNOSTIC DIVISION

#### MAY REPORT

#### MAY EXHIBIT

### ACTIVITY/REST

- Generalized muscle weakness
- Fatigue
- Nighttime pain; interruption of sleep, delayed falling asleep, or awakened by pain
- Does not feel well rested
- History of occupation or participation in sports activities that wear on a particular joint
- Inability to participate in occupational and/or recreational activities at desired level

- Decreased muscle strength and tone

### HYGIENE

- Difficulty performing activities of daily living (ADLs)
- Use of special equipment and/or mobility devices
- Need for assistance with some or all activities

### NEUROSENSORY

- Soft tissue swelling, nodules
- Muscle spasm, stiffness
- Joint deformities

### PAIN/DISCOMFORT

- Persistent disabling pain
- Pain—dull, aching, persistent in affected joint(s)
- Pain worsened by movement
- Difficulty walking due to pain
- Stiffness in joints, which is worse in the morning or after a period of inactivity

- Decreased range of motion (ROM) of affected joints
- Gait disturbances—effort to compensate for joint pain
- Guarding affected area
- Positioning to ease pain
- Self-focused

**MAY REPORT (continued)****MAY EXHIBIT (continued)****SAFETY**

- Traumatic injury and/or fractures affecting the joint
- History of inflammatory, debilitating arthritis—RA or osteoarthritis
- Congenital deformities

- Changes in gait
- Falls

**TEACHING/LEARNING**

- Current medication use—anti-inflammatories, analgesics, opioids, steroids, hormone replacement therapy (HRT), bone resorption inhibitor (e.g., denosumab [Prolia]), calcium supplements

**DISCHARGE PLAN CONSIDERATIONS**

- May need assistance with transportation, self-care activities, and homemaker or maintenance tasks
- Possible placement in rehabilitation or extended-care facility for continued therapy and assistance

► Refer to section at end of plan for postdischarge considerations.

**DIAGNOSTIC STUDIES****TEST****WHY IT IS DONE****WHAT IT TELLS ME**

- **X-rays:** Visualize and evaluate skeletal changes or damage, determine treatment options, and guide orthopedic surgery.
- **Bone scan, computed tomography (CT) scans, magnetic resonance imaging (MRI):** Nuclear scans to assess status of bones and joints.

May reveal destruction of articular cartilage, bony demineralization, fractures, soft tissue swelling, narrowing of joint space, joint subluxations, or deformity.

Determines extent of degeneration and rules out malignancy or infectious process.

**NURSING PRIORITIES**

1. Alleviate pain.
2. Prevent complications.
3. Promote optimal mobility.
4. Provide information about diagnosis, prognosis, and treatment needs.

**DISCHARGE GOALS**

1. Mobility increased.
2. Complications prevented or minimized.
3. Pain relieved or controlled.
4. Diagnosis, prognosis, and therapeutic regimen understood.
5. Plan in place to meet needs after discharge.

**NURSING DIAGNOSIS: acute Pain****May Be Related To**

Physical injury agents (e.g., surgical procedure, muscle spasms, preexisting chronic joint diseases)

**Possibly Evidenced By**

Self-report of intensity and characteristics of pain using standardized scale/instrument  
 Expressive behavior (e.g., restlessness, irritability)  
 Guarding behavior; protective behavior  
 Narrowed focus, self-focused  
 Changes in vital signs

(continues on page 732)

**NURSING DIAGNOSIS:** **acute Pain** (continued)**Desired Outcomes/Evaluation Criteria—Client Will****Pain Level NOC**

Report pain relieved or controlled.

Appear relaxed, able to rest or sleep appropriately.

**Pain Control NOC**

Demonstrate use of relaxation skills and diversional activities, as indicated by individual situation.

**ACTIONS/INTERVENTIONS****RATIONALE****Pain Management: Acute NIC****Independent**

Perform comprehensive assessment of pain, noting intensity (0 to 10, or similar coded scale), duration, and location. Determine if pain is at operative or different site, associated with ROM or weight-bearing, associated with vascular compromise or fever.

Maintain prescribed position of operated extremity.

Provide comfort measures—frequent repositioning, back rub—and diversional activities. Encourage stress management techniques, such as progressive relaxation, guided imagery, visualization, and meditation. Provide Therapeutic Touch, as appropriate.

Medicate on a round-the-clock schedule initially and well before activities or therapies if receiving prn dosing.

Investigate reports of sudden, severe joint pain with muscle spasms and changes in joint mobility, or sudden, severe chest pain with dyspnea and restlessness.

**Collaborative**

Collaborate in pain management plan as indicated, such as:

Opioids—use of patient-controlled analgesia (PCA) and/or targeted analgesia, such as epidural infusion or continuous femoral blockade (**initiated** perioperatively), along with intravenous NSAIDs such as ketorolac (Toradol)

Oral analgesics such as **opioid and nonopioid** analgesics (e.g., oxycodone [OxyContin], morphine sulfate extended-release capsules [Kadian, Avinza]); **anti-inflammatory drugs** (e.g., ibuprofen [Motrin], diclofenac [Voltaren]); **acetaminophen alone or in combination with opioids** (e.g., oxycodone and acetaminophen [Percocet], hydrocodone and acetaminophen [Vicodin]); **gabapentinoids** (e.g., gabapentin [Neurotin]; pregabalin [Lyrica])

Provides information on which to base and monitor effectiveness of interventions.

Reduces muscle spasm and undue tension on new prosthesis and surrounding tissues.

Reduces muscle tension, refocuses attention, promotes sense of control, and may enhance coping abilities in the management of discomfort or pain, which can persist for an extended period.

Total joint replacement (TJR) surgeries are known to be accompanied by moderate to severe pain from the reconstruction. Pain management is often complicated by client's age, comorbidities, and general deconditioned status before surgery. Effectively managing postoperative pain is essential for helping client achieve the best possible functional outcome (Rasul & Wright, 2016).

Early recognition of developing problems, such as dislocation of prosthesis or blood or fat pulmonary emboli, provides opportunity for prompt intervention and prevention of more serious complications.

Combination of different analgesics and techniques that act by different mechanisms (known as multimodal analgesia [MMA]) results in improved analgesic effect with lower adverse effects than with a single analgesic agent (Gregory et al., 2017; Hogg et al., 2014).

Relieves surgical pain and reduces muscle tension and spasm, which contribute to overall discomfort. Opioid infusion (including epidural) may be given during the first 24 to 48 hours for knee replacement or for breakthrough pain following hip replacement. Note: Use of ketorolac (Toradol) or other NSAID is contraindicated when client is receiving enoxaparin (Lovenox) therapy.

Optimal pain relief seems to result from combining a variety of medications. Each agent acts by a different mechanism and at a different site in the nervous system, thus providing maximal pain relief while minimizing adverse effects of any single agent (Wuhrman & Cooney, 2011).

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Apply and maintain ice packs, as indicated.	Cold therapy is considered part of a three-point approach to postoperative care: (1) pain medication, (2) elevation, and (3) icing. Studies support that cooling reduces bleeding and tissue edema in surgical area and lessens complications associated with excessive swelling, bruising, and inflammation. Note: Some clinicians recommend daily use of cold therapy as long as any pain remains (may be days or weeks).
Refer for/assist mobilization, such as early ambulation, transfers, gait training and other physical therapy modalities, or continuous passive motion (CPM) device (for knee joint) when used.	Improves circulation and range of motion of affected joint and muscles and can relieve muscle spasms related to disuse.

NURSING DIAGNOSIS: risk for Bleeding
<b>Possibly Evidenced By</b>
Trauma Treatment regimen (e.g., surgery, medications) Insufficient knowledge of bleeding precautions [e.g., during use of anticoagulant therapy]
<b>Desired Outcomes/Evaluation Criteria—Client Will</b>
<b>Blood Loss Severity NOC</b> Be free of active bleeding or excessive blood loss as evidenced by stable vital signs, usual mentation, absence of skin pallor, and adequate urinary output.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Bleeding Precautions NIC</b>	
<b>Independent</b>	
Monitor vital signs, including pulse and blood pressure and urinary output.	Tachycardia, falling blood pressure (BP), and low urinary output may reflect hypovolemia due to blood loss.
Assess skin color and moisture. Note changes in mentation or delay in return of usual mentation after recovery from anesthesia.	May reflect effects of anemia and hypoxemia from blood loss.
Monitor amount and characteristics of drainage on dressings and from suction device (e.g., Hemovac, Jackson-Pratt drain) when used. Note swelling in operative area.	May indicate excessive bleeding or hematoma formation, which can potentiate neurovascular compromise. Note: Drain is usually discontinued the second postoperative day (Shiel, 2017).
<b>Collaborative</b>	
Monitor laboratory studies, such as: Hemoglobin (Hgb), hematocrit (Hct)	Many clients will not require blood transfusions during or after joint replacement surgery due to improved surgical techniques. Those who do need transfusion may have low blood counts prior to surgery. Blood transfusion may be needed if blood loss would negatively affect cardiopulmonary status in the immediate postoperative period.
Administer IV fluids and donor or autologous blood transfusions, as needed.	Restores circulating volume to maintain perfusion. Note: Current management of postoperative anemia in elective TJR (when preoperative anemia is diagnosed) includes infusion of client's own red blood cells (autologous donation) donated and banked at least a month out from the procedure or use of the hormone erythropoietin (EPO) to increase red blood count. When an anemic client has considerable perioperative blood loss, salvaged blood collected from operative site during first 6 hours following procedure may be reinfused per protocol. Research continues on this practice to determine benefit vs risk (Jackson, 2010).

## NURSING DIAGNOSIS: risk for Infection

### Possibly Evidenced By

Alteration in skin integrity; invasive procedures (exposure of joint, implantation of foreign body)  
Decrease in hemoglobin, immunosuppression—long-term corticosteroid use

### Desired Outcomes/Evaluation Criteria—Client Will

#### Infection Severity NOC

Achieve timely wound healing, be free of purulent drainage or erythema, and be afebrile.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Infection Protection NIC</b>	
<i>Independent</i>	
Identify client's particular risk for developing surgical site (or other) infection.	Hip and knee replacements are the most frequently performed of all total joint surgeries and are most often done in people between the ages of 55 and 80. While age is not, in itself, a limiting factor for surgery, older clients are more likely to have comorbidities (e.g., diabetes, existing infections, malnutrition, anemia), which can impact postoperative healing. Note: Literature review shows that the leading cause of 30-day unplanned readmission after total knee arthroplasty (TKA) is deep or superficial surgical site infection (SSI) (12.1% for knee; 23.5% for hip) (Lovett-Carter et al, 2018).
Model and promote hand hygiene by staff and client.	Reduces risk of cross-contamination.
Use strict aseptic or clean technique, as indicated, to reinforce or change dressings and when handling drains. Instruct client not to touch or scratch incision.	Prevents contamination and risk of wound infection, which could require removal of prosthesis.
Maintain patency of drainage devices (e.g., Hemovac, Jackson-Pratt) when present. Note characteristics of wound drainage.	Drains reduce risk of infection by preventing accumulation of blood and secretions (medium for bacterial growth) in the joint space. Purulent, odorous drainage is indicative of infection, and continuous drainage from incision may reflect developing skin tract, which can potentiate infectious process.
Assess skin and incision color, temperature, and integrity; note presence of erythema, inflammation, and loss of wound approximation.	Provides information about status of healing process and alerts staff to early signs of surgical site infection.
Investigate reports of increased incisional pain and changes in characteristics of pain.	Deep, dull, aching pain in operative area may indicate developing infection in joint. Note: Infection can be devastating because once infection sets in, joint may not be salvageable and prosthetic loss may occur.
Monitor temperature. Note presence of chills.	Although temperature elevations are common in early postoperative phase, elevations occurring 5 or more days postoperatively and/or presence of chills usually require intervention to prevent more serious complications, such as sepsis, osteomyelitis, tissue necrosis, and prosthetic failure.
Encourage fluid intake coupled with a high-protein diet.	Maintains fluid and nutritional balance to support tissue perfusion and provide nutrients necessary for cellular regeneration and tissue healing.
<i>Collaborative</i>	
Maintain reverse or protective isolation, if appropriate.	May be done initially to reduce contact with sources of possible infection, especially in an elderly, immunosuppressed, or diabetic client.
Administer antibiotics, as indicated.	Used prophylactically in the operating room and for the first 24 hours to prevent infection. Late infections may require intravenous (IV) antibiotic treatments for several weeks, in an effort to save the prosthetic joint.

**NURSING DIAGNOSIS:** risk for peripheral Neurovascular Dysfunction**Possibly Evidenced By**

Orthopedic surgery; immobilization; mechanical compression (e.g., dressing, brace)  
Vascular obstruction

**Desired Outcomes/Evaluation Criteria—Client Will****Tissue Perfusion: Peripheral NOC**

Maintain function as evidenced by sensation and movement within normal limits for individual situation.  
Demonstrate adequate tissue perfusion as evidenced by palpable pulses, brisk capillary refill, warm or dry skin, and normal color.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Circulatory Care: Arterial [or] Venous Insufficiency NIC</b>	
<i>Independent</i>	
Palpate pulses. Evaluate capillary refill and skin color and temperature. Compare with unoperated limb.	Diminished or absent pulses, delayed capillary refill time, pallor, blanching, cyanosis, and coldness of skin reflect diminished circulation or perfusion. Comparison with unoperated limb provides clues as to whether neurovascular problem is localized or generalized.
Assess motion and sensation of operated extremity.	Increasing pain, numbness or tingling, and/or inability to perform expected movements (such as ankle-flexing) suggest nerve injury, compromised circulation, or dislocation of prosthesis, requiring immediate intervention.
Test sensation of peroneal nerve by pinch or pinprick in the dorsal web between first and second toe, and assess ability to dorsiflex toes after hip or knee replacement.	Position and length of peroneal nerve increase risk of direct injury or compression by tissue edema or hematoma.
Ensure that stabilizing devices (such as abduction pillow or splint device) are in correct position and are not exerting undue pressure on skin and underlying tissue. Avoid use of pillow or bed knee catch under knees.	Reduces risk of pressure on underlying nerves or compromised circulation to extremities.
Evaluate for calf tenderness, tension, and redness.	Although clinical signs are often not reliable in this population, surveillance should be carried out. Early identification of thrombus development and intervention may prevent embolus formation.
Encourage regular “foot pumps” throughout day.	Pushing the foot down, pointing toes, and pulling toes up toward the ceiling causes the calf to tighten and assists venous return to prevent blood pooling and reduce risk of deep vein thrombosis (DVT).
<i>Collaborative</i>	
Monitor laboratory studies, such as:	
Coagulation studies	Evaluates presence and degree of alteration in clotting mechanisms and effects of anticoagulant or antiplatelet agents when used.
Administer medications, as indicated, for example, low-molecular-weight heparins, enoxaparin (Lovenox), or fondaparinux (Arixtra).	Anticoagulants or antiplatelet agents may be used routinely to reduce risk of thrombophlebitis and pulmonary emboli. Note: Without prophylaxis, the incidence of DVT after total knee replacement (TKR) is 50% to 84%, and after total hip replacement (THR), 47% to 64%. With use of anticoagulation therapy, the incidence is reduced 22% to 57% after TKR and 6% to 24% after THR (Rasul & Wright, 2016).
Maintain intermittent compression stocking or foot/ankle compression boots (e.g., PlexiPulse™) when used.	Promotes venous return and prevents venous stasis, reducing risk of thrombus formation.

## NURSING DIAGNOSIS: impaired physical Mobility

### May Be Related To

Musculoskeletal impairment; joint stiffness; prescribed movement restrictions  
Pain; pharmaceutical agent  
Decrease in endurance; physical deconditioning  
Insufficient environmental support (e.g., physical, social, mobility aids)

### Possibly Evidenced By

Discomfort [reluctance/unwillingness to move]  
Limited range of motion; alteration in gait; difficulty turning  
Slowed or spastic movement

### Desired Outcomes/Evaluation Criteria—Client Will

#### Mobility NOC

Display increased strength, ROM, and function of affected joint and limb.

#### Ambulation NOC

Ambulate with assistance/assistive device as needed.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Positioning NIC</b> <i>Independent</i> Maintain affected joint in prescribed position and body in alignment when in bed. Medicate around the clock, or sufficient time before procedures and activities, so that client is able to participate. Turn on unoperated side using adequate number of personnel and maintaining operated extremity in prescribed alignment. Support position with pillows and wedges. Demonstrate and assist with transfer techniques and use of mobility aids, such as a trapeze, walker, crutches, or canes. Determine upper body strength and need for equipment to assist with ADLs, as appropriate. Involve in exercise program. Inspect skin; observe for reddened areas. Keep linens dry and wrinkle-free. Massage skin routinely. Protect operative heel, elevating whole length of leg with pillow and placing heel in offloading device if burning sensation reported or area reddened.	Provides for stabilization of prosthesis and reduces risk of injury during recovery from effects of anesthesia. Adequate analgesia is a priority to decrease pain, reduce muscle tension and spasm, and facilitate participation in therapy. Prevents dislocation of hip prosthesis and prolonged skin and tissue pressure, reducing risk of tissue ischemia and breakdown. Facilitates self-care and client's independence. Proper transfer techniques prevent shearing abrasions of skin and falls. Replacement of lower-extremity joint requires increased use of upper extremities for transfer, ADLs, and desired activities as well as use of ambulation devices. Prevents skin irritation or breakdown.
<b>Exercise Therapy: Joint Mobility NIC</b> Perform or assist with ROM to unoperated joints. Promote participation in rehabilitative exercise program, such as the following:  Total hip: Quadriceps and gluteal muscle setting, isometrics, leg lifts, dorsiflexion, and plantar flexion (ankle pumps) of the foot Total knee: Quadriceps setting, gluteal contraction, flexion and extension exercises, and isometrics	Client with degenerative joint disease can quickly lose function in unoperated joints during periods of restricted activity.  Contralateral joint may be nearly as painful as the surgical joint and may require careful and consistent treatment to maximize mobility. Strengthens muscle groups, increasing muscle tone and mass; stimulates circulation; and prevents decubitus ulcers.
Observe appropriate limitations based on specific joint; for example, avoid marked flexion or rotation of hip and flexion or hyperextension of leg; adhere to weight-bearing restrictions; and wear knee immobilizer, as indicated.	Active use of the joint may be painful but will not injure the joint. Continuous passive motion exercise may be initiated on the knee joint postoperatively, although its use is dependent on the particular surgeon and on the individual's needs.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Investigate sudden increase in pain and shortening of limb as well as changes in skin color, temperature, and sensation.	May be indicative of slippage of prosthesis or other complication, requiring medical evaluation and intervention (not typical in immediate postoperative period). Joint stress is to be avoided at all times during stabilization period to prevent dislocation of new prosthesis.
Encourage participation in ADLs.	Enhances self-esteem and promotes sense of control and independence.
Provide positive reinforcement for efforts.	Promotes a positive attitude and encourages involvement in therapy.
<b>Collaborative</b> Collaborate with physical and occupational therapists and rehabilitation specialist.	Client will require individualized activity and exercise program, ongoing assistance with movement, strengthening, and weight-bearing activities for an extended period of time, as well as use of adjuncts, such as walkers, crutches, canes, elevated toilet seat, pickup sticks, and so on.
Provide foam or flotation mattress.	Reduces skin and tissue pressure; limits feelings of fatigue and general discomfort.

### NURSING DIAGNOSIS: risk for Constipation

#### Possibly Evidenced By

[Effects of medications—anesthesia, opiate analgesics; decreased physical activity]  
 Insufficient fiber or fluid intake; inadequate dietary habits  
 Decrease in gastrointestinal (GI) motility  
 Recent environmental changes

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Bowel Elimination NOC

Regain/maintain usual pattern of bowel functioning.  
 Demonstrate behaviors to prevent problem.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Bowel Management NIC</b> <i>Independent</i>	
Identify individual risk factors. Determine current situation and possible impact on bowel function—surgery, new and chronic use of medications affecting intestinal functioning, age, or weakness.	Constipation is one of the most frequent complaints following surgery and during rehabilitation. If left untreated, constipation can lead to nausea and vomiting, bowel obstruction, or even sepsis, especially in the elderly.
Auscultate abdomen for presence, location, and characteristics of bowel sounds.	Reflects activity of GI tract.
Determine usual elimination pattern or frequency, characteristics of stool—color, consistency, amount—manner of constipation, and use of laxatives.	Provides baseline for comparison, promotes recognition of changes, and helps to establish a preventative plan.
Evaluate usual dietary and fluid intake; compare with current intake.	Client's usual diet and fluid intake may be marginal at best in promoting healthy bowel functioning, especially when combined with current postsurgical status.
Promote increased fluid intake, including water and high-fiber fruit juices; offer warm stimulating fluids, such as coffee, tea, and hot water.	Prevents dehydration and decreases reabsorption of water from the bowel, promoting softer stool and facilitating passage of stool.
Encourage early ambulation and exercise within client's limitation of activity. Assist with early mobility.	To stimulate and optimize GI function.
Provide privacy and routinely scheduled time for defecation based on usual pattern, as appropriate (e.g., bedside commode or toilet with elevated seat, after breakfast).	To facilitate return of normalcy in toileting routine.

(continues on page 738)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<b>Collaborative</b> Consult with dietitian or nutritionist, as indicated.	Helpful in providing a diet with balanced fiber and bulk that client can continue after discharge to improve consistency of stool and facilitate its passage.
Implement bowel program: administer routine stool softeners (e.g., docusate [Colace]); stool stimulants (e.g., bisacodyl [Dulcolax]), polyethylene glycol (Miralax); sennosides (e.g., Senokot, Ex-lax); bulk-forming agents (e.g., polycarbophil [FiberCon]), psyllium (Metamucil); saline laxatives (e.g., magnesium citrate) and enemas, as indicated.	Used to prevent or treat constipation.

**NURSING DIAGNOSIS:** **deficient Knowledge regarding condition, prognosis, treatment, self-care, and discharge needs**

**Risk Factors May Include**

Insufficient information; insufficient knowledge of resources  
Misinformation presented by others

**Possibly Evidenced By**

Insufficient knowledge  
Inaccurate follow-through of instructions  
Development of preventable complication

**Desired Outcomes/Evaluation Criteria—Client Will**

**Knowledge: Treatment Regimen NOC**

Verbalize understanding of surgical procedure and prognosis.  
Perform necessary procedures correctly, and explain reasons for the actions.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Teaching: Disease Process NIC</b> <i>Independent</i> Review disease process, surgical procedure, and future expectations.	Provides knowledge base from which client can make informed choices. The majority of total joint surgeries are elective, and preoperative education is done in some form in the surgeon's office or in the admitting facility. Postsurgical review of process and expectations may be needed or desired.
Encourage alternating rest periods with activity.	Conserves energy for healing and prevents undue fatigue, which can increase risk of injury or fall.
Emphasize importance of continuing prescribed exercise and rehabilitation program—crutch or cane walking, weight-bearing exercises, stationary bicycling, hydrotherapy, swimming.	Increases muscle strength and joint mobility. Most clients will be involved in formal outpatient rehabilitation, home-care programs, or be followed in extended-care facilities by physical therapists. Note: Client with cemented joint replacement can weight-bear as tolerated (WBAT) unless the operative procedure involved a soft tissue repair or internal fixation of bone (following fracture). Client with cementless joint replacement is put on partial weight-bearing (PWB) or toe-touch weight-bearing (TTWB) for several weeks to allow maximum bony ingrowth to take place. A knee immobilizer sometimes is worn after total knee replacement until quadriceps strength is regained (Iverson, 2012; Rasul & Wright, 2016).
Review activity limitations, depending on joint replaced: for hip or knee—sitting for long periods or in low chair or toilet seat, recliner; jogging, jumping, excessive bending, lifting, twisting, or crossing legs.	Prevents undue stress on implant. Long-term restrictions depend on individual situation and physician protocol.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Discuss need for safe environment in home, including removing scatter rugs and unnecessary furniture, and use of assistive devices, such as hand rails in tub and toilet, raised toilet seat, and cane for long walks.	Reduces risk of falls and excessive stress on joints.
Review and have client or caregiver demonstrate incisional or wound care, as indicated.	Promotes independence in self-care, reducing risk of complications.
Identify signs and symptoms requiring medical evaluation: fever or chills, incisional inflammation, unusual wound drainage, pain in calf or upper thigh, or development of sore throat or dental infections.	Bacterial infections require prompt treatment to prevent progression to osteomyelitis in the operative area and prosthesis failure, which could occur at any time, even years later.
Review drug regimen, for example, anticoagulants or antibiotics prior to invasive procedures (e.g., tooth extraction).	Prophylactic therapy may be necessary for a prolonged period after discharge to limit risk of thromboemboli and infection. Procedures known to release bacteria into the bloodstream can lead to infection, osteomyelitis, and prosthesis failure.
Identify bleeding precautions—for example, use of soft toothbrush, electric razor, avoidance of trauma, or forceful blowing of nose—and necessity of routine laboratory follow-up.	Reduces risk of therapy-induced bleeding or hemorrhage.
Encourage intake of balanced diet, including roughage and adequate fluids.	Enhances healing and feeling of general well-being. Promotes bowel and bladder function during period of altered activity.
Discuss continuation of supplemental calcium and vitamin D, hormone replacement, bisphosphonates, and the like as indicated.	Promotes bone health in clients with decreased bone density or who are at risk for osteoporosis.

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

**In addition to considerations in surgical intervention plan of care:**

- **risk for Falls**—postoperative conditions, impaired physical mobility, decreased lower extremity strength, impaired balance, use of assistive devices
- **risk for Constipation**—insufficient physical activity, decreased motility of gastrointestinal tract, insufficient fiber/fluid intake, side effects of medications
- **Self-Care deficit**—musculoskeletal impairment, weakness, fatigue, pain
- **Impaired Home Maintenance**—impaired functioning, inadequate support systems, unfamiliarity with neighborhood resources

# Integumentary Disorders

## BURNS: THERMAL, CHEMICAL, AND ELECTRICAL—ACUTE AND CONVALESCENT PHASES

**I. Pathophysiology**—local and systemic response affecting skin and/or other tissues depending on cause of burn injury and physiological response (Hettiaratchy & Dziewulski, 2004; Vorstenbosch & Buschel, 2017)

a. Local responses

- i. Coagulation: occurs at the point of maximum damage, causing irreversible tissue loss due to coagulation of the constituent proteins
- ii. Stasis: area characterized by decreased tissue perfusion that is potentially salvageable unless additional insults, such as prolonged hypotension, infection, or edema, occur, converting this zone into an area of complete tissue loss
- iii. Hyperemia: Outermost area has increased tissue perfusion, and tissue will recover unless severe sepsis or prolonged hypoperfusion occurs.

b. Systemic response—Cytokines and other inflammatory mediators are released at the site of burn injuries with total body surface area (TBSA) of 30% or greater.

- i. Cardiovascular: Increased capillary permeability leads to shift of intravascular proteins and fluids into the interstitial space, followed by vasoconstriction and decreased myocardial contractility; combined with fluid loss from the burn wound, systemic hypotension and organ hypoperfusion occur.
- ii. Respiratory: Bronchoconstriction occurs in response to inflammatory mediators, which, in severe inhalation injury, can cause acute respiratory distress syndrome (ARDS).
- iii. Metabolic: Rate increases up to three times the baseline rate, resulting in breakdown of muscle tissue.
- iv. Immunological: Immune suppression response occurs.

**II. Classification**—by burn wound and depth

- a. Superficial partial-thickness (first-degree) burns: affect only the epidermis; skin is often warm and dry, and wounds appear bright pink to red with minimal edema and fine blisters, if present
- b. Moderate partial-thickness (second-degree) burns: include the epidermis and dermis; wounds appear red to pink with moderate edema and blisters that may be intact or draining
- c. Deep partial-thickness (second-degree) burns: extend into the deep dermis; wounds are drier than moderate partial-

thickness burns and appear pale pink to pale ivory, with moderate edema and blisters

- d. Full-thickness (third-degree) burns: include all layers of skin and subcutaneous fat and may involve the muscle, nerves, and blood supply; wounds have a dry, leathery texture and appearance varies from white to cherry-red to brown or black, with blistering uncommon; absence of pain in the center, but the edges of the burn wound may have heightened sensation
- e. Full-thickness, subdermal (fourth-degree) burns: involve all skin layers as well as muscle, organ tissue, and bone, with charring. Fourth-degree burns result from prolonged exposure to the usual causes of third-degree burns.

**III. Types**

- a. Thermal: most common type of burn: occurs because of contact with hot substances, including flame, hot liquids, hot solid objects, steam, friction, or exposure to extremely cold objects (e.g., snow, nitrogen, dry ice). Flame burns are often associated with smoke/inhalation injury. *Note:* It is reported that 5% to 10% of all combat injuries include burns, often of the hands and head (Renz & Cancio, 2012).

**P** The majority of burn injuries in children are scald injuries resulting from hot liquids, occurring most commonly in children aged 0 to 4 years (Toon et al, 2011). At later ages, a large number of heat sources (e.g., hot surface, liquid scald, grease scald, radiation, chemicals) cause burn injury in children (Peck, 2017; Vorstenbosch & Buschel, 2017). Burns in older children and teenagers, especially boys, are often associated with risk-taking behaviors, such as careless use of flammable substances and fireworks (Dowshen, 2017).

- b. Chemical: contact with a caustic substance (acid or alkaline); degree of injury dependent on type and content as well as concentration and temperature of injuring agent. Although injuries do occur at home, the risk of sustaining a chemical burn is much greater in the workplace, especially in businesses and manufacturing plants that use large quantities of chemicals (Davis, 2017).

- c. Electrical: Current travels through the body along the pathway of least resistance (i.e., nerves offer the least resistance and bones the greatest resistance), generating heat in proportion to resistance offered; degree of injury

- dependent on type/voltage of current with underlying injury more severe than visible injury. Electrical injuries are responsible for 3% to 5% of all burn unit admissions and **P** cause 2% to 3% of emergency department burn visits in the pediatric population (Cushing & Wright, 2017).
- d. Radiation: These burns do not present as typical burns but rather dermatitis. Symptoms of radiation dermatitis include hair loss, dry or wet peeling skin (desquamation), decreased sweating, edema, ulcerations, bleeding, and skin cell death. Radiation burns are caused by exposure to ionizing radiation, most commonly overexposure to ultraviolet rays—UVA and UVG (e.g., the sun, sunlamps, tanning booths) or high exposure to x-rays, including radiotherapy (e.g., cancer therapy). The radiation types of greatest concern are thermal radiation, radiofrequency energy, ultraviolet light, and ionizing radiation. Refer to CP: Cancer: general considerations for related assessments.
  - e. Inhalation: Inhalation burns can occur concurrently with thermal (flame) or chemical burns, are complications of those burns. Inhalation injury is more common in adults and can present as an isolated injury or in combination with surface area burns. Initially, the heat generated during combustion can cause significant thermal injury to the upper airway, requiring aggressive early airway intervention. For example, manufacturing methamphetamine can cause both thermal and chemically associated inhalation injuries.
  - f. Risk factors: substance abuse, careless smoking, cultural practices, socioeconomic status (e.g., overcrowded living conditions, insufficient parental supervision of children, lack of safety precautions), and violence, including abuse and neglect, such as with those aged 4 years and under or those aged 65 years and older. **P** Note: Severe burns are reported in an estimated 10% of all children suffering physical abuse (Maguire et al, 2008).

#### IV. Statistics

- a. Morbidity: 486,000 burn injuries require medical attention in the United States annually. In 2016, there were approximately 40,000 burn-related hospitalizations in the United States, 30,000 of which were at specialized burn centers (American Burn Association [ABA], 2016). In 2016, the ABA reported a 96.8% survival rate in clients discharged from burn care centers.
- b. Mortality: In 2010, the National Institutes of Health (NIH) reported that the number of burn fatalities in the United States had declined dramatically, to about 3800 a year (NIH, 2010). The use of smoke detectors has significantly reduced the severity of burn injuries (estimated 80% reduction in mortality) (Vorstenbosch & Buschel, 2017). A direct but inverse relationship exists between age and survival for any burn size. While the mortality of a 40% TBSA burn in a 20-year-old is approximately 8%, the mortality of this same injury in someone older than 70 years is 94% (Vorstenbosch & Buschel, 2017). **P** In children, a burn size of 60% TBSA (and probable inhalation injury) was associated with a higher incidence of multiorgan failure, infections, sepsis, and death (Kraft et al, 2012). Respiratory failure and sepsis were found to be leading causes of death in severely burned children, with acute lung injury (ALI) and respiratory distress syndrome (ARDS) accounting for 40% to 50% of all deaths (Williams et al, 2009).
- c. Cost: Hospitalizations for burn survivors represent only 1% of all injuries in the United States, but direct costs of treatment are reportedly more than \$10.4 billion per year (Mater, 2015), at roughly \$24,000 per person hospital stay (Agency for Healthcare Research and Quality, 2015), with another \$3.3 billion spent in outpatient burn care (Paradigm Outcomes, 2013).

#### G L O S S A R Y

**The American Burn Association (ABA) criteria for burn center care (for adults):** (1) partial-thickness burns greater than 10% total body surface area (TBSA); (2) burns that involve the face, hands, feet, genitalia, perineum, or major joints; (3) third-degree burns in any age group; (4) electrical and chemical burns; (5) inhalation injury; (6) burn injury in individual with preexisting medical disorders that could complicate management, prolong recovery, or affect mortality; (7) patient with burns and concomitant trauma (such as fractures) in which the burn injury poses the greatest risk of morbidity or mortality (additional criteria can apply for children, as well as other situations (ABA, n.d.).

**Catabolism:** Breaking down of muscle tissue.

**Dermis:** Inner layer of skin, which contains blood and lymph vessels, hair follicles, and glands.

**Epidermis:** Outermost layer of skin, made up of flat, scalelike cells called squamous cells.

**Total body surface area (TBSA):** The “rule of nines” estimates the extent of TBSA involved in a burn injury to guide treatment. Major anatomic areas of the body are divided into percentages: in adults, 9% for the head and neck, 9% for each upper extremity, 18% to each of the anterior and posterior portions of the trunk, 18% to each lower extremity, and 1% to the perineum and genitalia. The client’s palm area represents approximately 1% of TBSA and can be helpful in calculating scattered areas of involvement. **P** In an infant, 18% for the head and neck, 9% for each upper extremity, 18% to each of the anterior and posterior portions of the trunk, 14% to each lower extremity, 1% to the perineum and genitalia, and palm area approximately 1%.

## CARE SETTING

Client with burns is admitted to a hospital or burn center for acute care and, during the rehabilitation phase, may be cared for in a subacute or rehabilitation unit.

## CLIENT ASSESSMENT DATABASE

Data depend on type, severity, and body surface area of burn(s), as well as the stage (i.e., acute or rehabilitation).

### DIAGNOSTIC DIVISION MAY REPORT

### MAY EXHIBIT

#### ACTIVITY/REST

- Decreased strength, endurance
- Limited range of motion (ROM) of involved areas
- Altered muscle mass and tone

#### CIRCULATION

(with burn injury of more than 20% TBSA)

- Hypotension (shock)
- Peripheral pulses diminished distal to extremity injury; generalized peripheral vasoconstriction with loss of pulses, mottling of skin, and coolness (electrical shock)
- Tachycardia (shock, anxiety, pain)
- Dysrhythmias (electrical injury; electrolyte imbalances)
- Tissue edema formation (all burns)

#### EGO INTEGRITY

- Feeling scared, self-conscious, conspicuous, angry, embarrassed, different
- Concerns about family, job, finances, disfigurement

- Anxiety, irritability
- Crying, depression
- Hostility, aggressive behavior
- Denial, withdrawal

#### ELIMINATION

- Urinary output decreased or absent during emergent phase; color may be pink from damaged red blood cells (RBCs) or reddish-black if myoglobin present, indicating deep-muscle damage
- Diuresis—after capillary leak sealed and fluids mobilized back into circulation
- Bowel sounds decreased or absent, especially in cutaneous burns of more than 20% TBSA, because stress reduces gastric motility, peristalsis

#### FOOD/FLUID

- Anorexia, nausea, vomiting
- Weight loss

- Generalized tissue edema—swelling is rapid and may be extreme in early hours after injury

**MAY REPORT (continued)****NEUROSENSORY**

- Mixed areas of numbness, tingling, burning pain
- Changes in vision, decreased visual acuity (electrical shock)

**MAY EXHIBIT (continued)**

- Changes in orientation, affect, behavior
- Decreased deep tendon reflexes (DTRs), reflexes, and sensation in injured extremities
- Seizure activity (electrical injury)
- Paralysis (electrical injury to nerve pathways)
- Corneal lacerations, retinal damage (electrical shock)
- Rupture of tympanic membrane (electrical shock)

**PAIN/DISCOMFORT**

- Pain varies—first-degree burns are extremely sensitive to touch, pressure, air movement, and temperature changes.
- Second-degree moderate-thickness burns are very painful, whereas pain response in second-degree deep-thickness burns is dependent on intactness of nerve endings.
- Third-degree burns: Traditional teaching is that full-thickness burns are painless due to the cutaneous nerve endings being destroyed. However, in a recent study, 75% of individuals with full-thickness burns reported pain. The authors suggest that even in full-thickness injury, there are still some intact nerve endings (Singer et al, 2015).

**RESPIRATION**

- History of confinement in a closed space during a fire; prolonged exposure to flames or strong chemicals (possibility of inhalation injury)

- Guarding behavior, protective positioning
- Expressive behavior, such as restlessness, moaning, crying
- Self-focusing; facial mask
- Changes in blood pressure (BP), pulse, respiratory rate

**SAFETY**

- History of previous burns or other injuries
- Engaging in risky behavior—substance abuse, sporting activities during thunderstorm, working near high power lines
- Lack of safety practices; for example, no smoke detector, smoking in bed, wearing loose-fitting clothing around open flame, improper use or storage of caustic chemicals
- Sensory impairments limiting detection of heat or cold
- Episodes of violence or abuse

- Facial burns, hoarseness, wheezy cough, soot in the nose or mouth, flecks of carbon in the sputum, lip edema, drooling or inability to swallow oral secretions, and cyanosis (indicative of inhalation injury) (Culleiton & Simko, 2013)
- Breath sounds—crackles (pulmonary edema), stridor (laryngeal edema), profuse airway secretions, wheezing (rhonchi)
- Thoracic excursion may be limited in presence of circumferential chest burns.

**SKIN**

- **General:** Exact depth of tissue destruction may not be evident for 3 to 5 days because of the process of microvascular thrombosis in some wounds; unburned skin areas may be cool, clammy, and pale, with slow capillary refill in the presence of decreased cardiac output as a result of fluid loss or shock state.
- **Flame injury:** There may be areas of mixed depth of injury because of varied intensity of heat produced by burning clothing; singed nasal hairs; dry, red mucosa of nose and mouth; blisters on posterior pharynx, circumoral and/or circumnasal edema.
- **Chemical injury:** Wound appearance varies according to causative agent; skin may be yellowish-brown with soft leather-like texture; blisters, ulcers, necrosis, or thick eschar. *Note:* Injuries are generally deeper than they appear cutaneously, and tissue destruction can continue for up to 72 hours after injury.
- **Electrical injury:** The external cutaneous injury is usually much less than the underlying necrosis; appearance of wounds varies and may include entry and exit (explosive) wounds of current, arc burns from current moving in close proximity to body, and thermal burns due to ignition of clothing.
- **Other:** Presence of fractures, dislocations (concurrent falls, motor vehicle accident; tetanic muscle contractions due to electrical shock)

(continues on page 744)

**TEACHING/LEARNING**

- Use of sedatives, alcohol, tobacco, and street drugs
- Cultural beliefs and practices

**DISCHARGE PLAN CONSIDERATIONS**

- May require assistance with treatments, wound care and supplies, self-care activities, homemaker and maintenance tasks, transportation, finances, and vocational counseling
- Changes in physical layout of home or living facility other than home during prolonged rehabilitation

► Refer to section at end of plan for postdischarge considerations.

**DIAGNOSTIC STUDIES****WHY IT IS DONE****WHAT IT TELLS ME****BLOOD TESTS**

- **Complete blood count (CBC):** Battery of screening tests, which typically includes hemoglobin (Hgb); hematocrit (Hct); red blood cell (RBC) count morphology, indices, and distribution width index; platelet count and size; white blood cell (WBC) count and differential.
  - **Arterial blood gases (ABGs) and pulse oximetry:** Describe the assessment of arterial blood levels of oxygen ( $\text{PaO}_2$ ) and carbon dioxide ( $\text{PaCO}_2$ ). Typically, blood pH (acidity) is measured simultaneously with ABGs.
  - **Carboxyhemoglobin (COHgb):** Compound that is formed when inhaled carbon monoxide combines with Hgb, binding more tightly than oxygen and rendering the Hgb incapable of transporting oxygen.
  - **Serum electrolytes:** Substance that will dissociate into ions in solution and acquire the capacity to conduct electricity. Electrolytes include sodium, potassium, chloride, calcium, and phosphate.
  - **Serum glucose:** Simple sugar that is a major energy source for all cellular and bodily functions.
  - **Albumin, globulin, and albumin/globulin ratio:** Albumin and globulin make up most of the protein within the body and are measured in the total protein of the blood and other body fluids. Albumin proteins are normally higher than globulin and are expressed in ratio.
  - **Blood urea nitrogen (BUN) and creatinine (Cr):** BUN and Cr are waste products in the blood from the breakdown of protein and are filtered by the kidneys.
- Initial increased Hct suggests hemoconcentration due to fluid shift or loss. Later, Hct and RBCs may be decreased because of heat damage to vascular endothelium. WBCs may be elevated due to inflammatory response to injury.
- Baseline is especially important with suspicion of inhalation injury. Reduced  $\text{PaO}_2$  and increased  $\text{PaCO}_2$  may be seen with carbon monoxide poisoning. Acidosis may occur because of reduced renal function and loss of compensatory respiratory mechanisms.
- Elevated percentage reflects the extent to which normal transport of oxygen has been negatively affected. Elevation of more than 10% indicates inhalation injury in a nonsmoker. Toxic exposure with levels greater than 40% to 50% can result in loss of consciousness, seizures, coma, and death (70%) (Lafferty et al, 2017).
- Potassium level may be initially elevated because of injured tissues, RBC destruction, and decreased renal function; hypokalemia can occur when diuresis starts; and magnesium level may be decreased. Sodium level may initially be decreased with body water losses; hypernatremia can occur later as renal conservation occurs.
- Elevation reflects stress response; hypoglycemia can occur due to decreased glycogen stores.
- Albumin/globulin ratio may be reversed because of loss of protein in edema fluid.
- Elevation reflects decreased renal perfusion or function; however, the level of Cr can become elevated because of tissue injury.

WHY IT IS DONE (continued)	WHAT IT TELLS ME (continued)
<b>URINE TESTS</b>	
• <b>Urinalysis:</b> Screening test to evaluate renal function and detect substances or cellular material reflecting injury.	Presence of albumin, Hgb, and myoglobin indicates deep-tissue damage and protein loss—especially seen with serious electrical burns. Reddish-black color of urine indicates presence of myoglobin.
<b>ASSOCIATED TESTS</b>	
• <b>Photographs of burns:</b> Documents burn wound at time of admission.	Provides baseline to evaluate healing process.
• <b>Laser Doppler:</b> Measures microvascular blood flow in dermis.	Useful in predicting the depth of burn wounds and the potential for early excision and grafting of burn wounds.
• <b>Magnetic resonance imaging (MRI) scan:</b> Scan that uses magnetic fields to produce two- or three-dimensional images of organs inside the body.	Detects tissue edema—a manifestation of cell membrane damage that begins to accumulate minutes after electrical injury from increased vascular permeability and extravasation of intracellular contents.
• <b>Wound cultures:</b> Drainage or material from burn area is grown in the laboratory on nutrient-enriched media to identify presence of microorganisms such as bacteria or fungi.	May be obtained for baseline data and repeated periodically to evaluate for wound infection and/or effectiveness of antimicrobial therapies.
• <b>Chest x-ray:</b> Evaluates organs and structures within the chest for symptoms of disease.	May appear normal in early postburn period even with inhalation injury; however, a true inhalation injury presents as infiltrates, often progressing to whiteout on x-ray.
• <b>Upper airway endoscopy and fiber-optic bronchoscopy—also known as direct or indirect laryngoscopy:</b> Direct visualization of upper airways by means of either a rigid or a flexible bronchoscope.	Useful in diagnosing extent of inhalation injury in the high-risk client; findings can include edema, hemorrhage, and/or ulceration of upper respiratory tract.
• <b>Pulmonary function studies—forced expiratory volume (<math>FEV_1</math>) and peak flow volume loop:</b> Evaluates respiratory status.	Provides noninvasive assessment of effects and extent of inhalation injury. Airway obstruction causes a decrease in $FEV_1$ and peak flow. <i>Note:</i> Full resolution of pulmonary function abnormalities may take several months.
• <b>Ventilation-perfusion lung scan:</b> Uses inhaled and injected radioisotopes to measure breathing and circulation in all areas of the lungs.	May be done to determine extent of inhalation injury.
• <b>Electrocardiogram (ECG):</b> Record of the electrical activity of the heart, providing important information concerning the spread of electricity to the different parts of the heart.	Signs of myocardial ischemia and dysrhythmias may occur with electrical burns.
• <b>Cardiac enzymes (e.g., creatinine phosphokinase-muscle band [CPK-MB] isoenzyme):</b> A group of enzymes normally found in heart tissue and released into the bloodstream in increased concentration when the heart muscle is damaged.	Myocardial infarction (MI) can be a complication of electrical injury or postinjury resuscitation, causing elevation of cardiac enzymes. <i>Note:</i> Skeletal muscle cells contain as much as 20% to 25% CK-MB fraction, suggesting that elevation of this enzyme may reflect skeletal rather than myocardial damage (Vande Ven & Podda, 2017).

## NURSING PRIORITIES

1. Maintain patent airway and respiratory function.
2. Restore hemodynamic stability and circulating volume.
3. Alleviate pain.
4. Prevent complications.
5. Provide emotional support for client and significant other (SO).
6. Provide information about condition, prognosis, and treatment.

## DISCHARGE GOALS

1. Homeostasis achieved.
2. Pain controlled or reduced.
3. Complications prevented or minimized.
4. Current situation dealt with realistically.
5. Condition, prognosis, and therapeutic regimen understood.
6. Plan in place to meet needs after discharge.

**NURSING DIAGNOSIS:** **risk for ineffective Airway Clearance****Possibly Evidenced By**

Exposure to smoke

Airway spasm, excessive mucous; retained secretions, exudates in the alveoli

**Desired Outcomes/Evaluation Criteria—Client Will****Respiratory Status NOC**

Demonstrate clear breath sounds; respiratory rate within normal range; and be free of dyspnea and cyanosis.

Display oxygen saturation within normal range.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Respiratory Monitoring NIC</b> <i>Independent</i> Obtain history of burn exposure. Note presence of preexisting respiratory conditions and any history of smoking.	Causative burn injury agent (e.g., flames, chemicals), duration of exposure, and whether exposed in closed or open space predict probability of inhalation injury. Type of material burned, such as wood, plastic, or wool, suggests type of toxic gas exposure. Preexisting conditions increase the risk of respiratory complications.
Assess gag and swallow reflexes; note upper airway burns, drooling, inability to swallow, hoarseness, and wheezy cough.	Suggestive of inhalation injury, which may develop over several days.
Monitor respiratory rate, rhythm, and depth, and measure pulse oximetry regularly. Note presence of pallor or cyanosis and carbonaceous or pink-tinged sputum.	Tachypnea, use of accessory muscles, decreasing oxygen level, pallor or cyanosis, and changes in sputum if client is coughing suggest developing respiratory distress and need for medical intervention.
Auscultate lungs, noting stridor, wheezing, crackles, diminished breath sounds, and brassy cough.	Airway obstruction and respiratory distress can occur very quickly or may be delayed, for example, up to 3 days after burn.
Note presence of pallor or cherry-red color of unburned skin.	Suggests presence of hypoxemia or carbon monoxide requiring additional evaluation and prompt intervention.
Investigate changes in behavior and mentation, such as restlessness, agitation, and confusion.	Although often related to pain, changes in consciousness may reflect developing, worsening hypoxia or effects of inhaled toxins, especially carbon monoxide.
Monitor 24-hour fluid balance, noting variations or changes.	Fluid shifts or excess fluid replacement increase risk of pulmonary edema. Note: Inhalation injury increases fluid demands as much as 35% or more because of edema and fluid shifts.
<b>Airway Management NIC</b> Elevate head of bed (if trauma condition allows). Avoid use of pillow under head, as indicated.	Promotes optimal lung expansion and respiratory function. When head and neck burns are present, a pillow can inhibit respiration, cause necrosis of burned ear cartilage, and promote neck contractures.
Encourage coughing, deep-breathing exercises, and frequent position changes.	Promotes lung expansion, mobilization, and drainage of secretions.
Suction, if necessary, with extreme care, maintaining sterile technique.	Helps maintain clear airway but should be done cautiously because of mucosal edema and inflammation. Sterile technique reduces risk of infection.
Promote voice rest, but assess ability to speak and/or swallow oral secretions periodically.	Increasing hoarseness or decreased ability to swallow suggests increasing tracheal edema and may indicate need for prompt intubation.
<b>Collaborative</b> Administer humidified oxygen via appropriate route, for example, a face mask.	Oxygen corrects hypoxemia and acidosis. Humidity decreases drying of respiratory tract and reduces viscosity of sputum.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Monitor serial ABGs.	Baseline is essential for further assessment of respiratory status and as a guide to treatment. $\text{PaO}_2$ less than 50, $\text{PaCO}_2$ greater than 50, and decreasing pH reflect smoke inhalation and developing pneumonia or acute respiratory distress syndrome (ARDS). Note: Pulse oximetry can be monitored continuously while respirations/oxygenation are compromised.
Monitor carboxyhemoglobin (COHgb) levels, if indicated.	Client with inhalation injury may be monitored for elevated carbon monoxide levels, although not all clients with inhalation injury show elevated COHgb. Note: Neurologic abnormalities and a history of loss of consciousness are the primary clinical features used to define severe CO toxicity. Note: Hyperbaric oxygenation therapy (HOT) may be considered in client with COHgb levels >25%, who is unconsciousness or has other neurologic findings, cardiovascular dysfunction, pulmonary edema, or severe metabolic acidosis (Lafferty et al, 2017).
Review serial chest x-rays.	Changes reflecting atelectasis or pulmonary edema may not occur for 2 to 3 days after burn injury.
Provide or assist with chest physiotherapy and incentive spirometry, as indicated.	Chest physiotherapy drains dependent areas of the lung, and incentive spirometry may be done to improve lung expansion, thereby promoting respiratory function and reducing atelectasis. Note: Bronchoscopy may be done to remove endotracheal debris.
Prepare for, or assist with, intubation or tracheostomy and mechanical ventilation, as indicated.	Intubation and mechanical support is required when airway edema or circumferential burn injury interferes with respiratory function and oxygenation. If client develops signs of respiratory failure or ARDS, mechanical ventilation and intensive respiratory care are required. (Refer to CP: Respiratory Failure/Ventilatory Assistance.)

### NURSING DIAGNOSIS: risk for deficient Fluid Volume

#### Possibly Evidenced By

Fluid loss through abnormal routes—burn wounds; hemorrhagic losses  
Factors influencing fluid needs—hypermetabolic state  
Deviations affecting fluid intake

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Fluid Balance NOC

Demonstrate adequate fluid balance as evidenced by appropriate urinary output with normal specific gravity, stable vital signs, and moist mucous membranes.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Shock Prevention NIC</b> <i>Independent</i> Monitor vital signs and central venous pressure (CVP). Note capillary refill and strength of peripheral pulses.	Serves as a guide to fluid replacement needs and assesses cardiovascular response to fluid loss and fluid shifts. Note: The metabolic rate increases proportionally with burn size. A 15% to 20% TBSA burn injury initiates a catabolic response, including impaired immunity and accentuating fluid shifts. The burned client will initially have a low cardiac index and be extremely vasodilated (causing drop in blood pressure), then will go into a hyperdynamic state with tachycardia and increased cardiac output (Gauglitz & Williams, 2017).

(continues on page 748)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Monitor urinary output and specific gravity. Observe urine color and Hematest, as indicated.	Generally, fluid replacement should be titrated to ensure average urinary output of 30 to 50 mL/hr in the adult. Urine can appear red to black due to muscle destruction causing release of myoglobin.
Estimate wound drainage and insensible losses.	Increased capillary permeability, protein shifts, inflammatory process, and evaporative losses greatly affect circulating volume and urinary output, especially during initial 24 to 72 hours after burn injury.
Maintain cumulative record of amount and types of fluid intake.	During fluid resuscitation, there is fine line between adequate resuscitation and one that is associated with the deleterious effects of fluid overload.
Weigh daily.	Fluid replacement formulas partly depend on admission weight and subsequent changes. A 15% to 20% weight gain can be anticipated in the first 72 hours during fluid replacement, with return to preburn weight approximately 10 days after burn.
Measure circumference of burned extremities, as indicated.	May be helpful in estimating extent of edema and fluid shifts affecting circulating volume and urinary output.
Investigate changes in mentation.	Deterioration in the level of consciousness may indicate inadequate circulating volume and reduced cerebral perfusion.
Observe for gastric distention, hematemesis, and tarry stools. Hematest nasogastric (NG) drainage and stools periodically.	Stress (Curling's) ulcer occurs in up to half of all severely burned clients and can occur as early as the first week. Clients with burns more than 20% of TBSA are at risk for mucosal bleeding in the gastrointestinal (GI) tract during the acute phase because of decreased splanchnic blood flow and reflex paralytic ileus.
<b>Collaborative</b>	
Insert and maintain indwelling urinary catheter.	Allows for close observation of renal function and prevents urinary retention. Retention of urine with its by-products of tissue cell destruction can lead to renal dysfunction and infection.
Insert/maintain large-bore intravenous (IV) catheter(s).	Accommodates rapid infusion of fluids.
Administer calculated IV replacement of fluids, electrolytes, plasma, and albumin.	Fluid resuscitation replaces lost fluids and electrolytes and helps prevent complications, such as shock and acute tubular necrosis (ATN). Replacement formulas vary, such as Brooke, Evans, or Parkland, but all are based on extent of burn injury, body weight, and amount of urinary output. Note: Once initial fluid resuscitation has been accomplished (usually with lactated Ringer's solution), a steady rate of fluid administration is preferred to boluses, which may increase interstitial fluid shifts and cardiopulmonary congestion. <b>P</b> The rate of fluid administration should be titrated to maintain a urine output of 0.5 mL/kg/h in older children (>50 kg). In small children, fluid should be maintained to produce urine output of approximately 1 mL/kg/h (Oliver, 2017).
Monitor laboratory studies, such as Hgb/Hct, electrolytes, and urine sodium.	Identifies blood loss, RBC destruction, and fluid and electrolyte replacement needs. Urine sodium less than 10 mEq/L suggests inadequate fluid resuscitation. Note: During first 24 hours after burn, hemoconcentration is common because of fluid shifts into the interstitial space.
Administer medications, as indicated, such as the following:	
Diuretics, for example, mannitol (Osmotrol)	May be indicated to enhance urinary output and clear tubules of debris to prevent necrosis if acute renal failure (ARF) is present.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Potassium	Although hyperkalemia often occurs during first 24 to 48 hours due to tissue destruction, subsequent replacement may be necessary because of large urinary losses.
Antacids, for example, calcium carbonate (Titrалac) and magaldrate (Riopan) and histamine inhibitors, for example, cimetidine (Tagamet) and ranitidine (Zantac)	Antacids may reduce gastric acidity; histamine inhibitors decrease production of hydrochloric acid to reduce risk of gastric irritation or bleeding.
Add electrolytes to water used for wound debridement, as indicated.	Washing solution that approximates tissue fluids may minimize osmotic fluid shifts.

## NURSING DIAGNOSIS: acute Pain

### May Be Related To

Physical injury agents (e.g., destruction of skin and tissues, edema formation, wound debridement)

### Possibly Evidenced By

Self-report of intensity and characteristics of pain using standardized pain scale/instrument  
Expressive behavior (e.g., irritability, restlessness, crying)  
Narrowed focus; facial expression of pain—grimacing  
Guarding behavior  
Changes in vital signs

### Desired Outcomes/Evaluation Criteria—Client Will

#### Pain Level NOC

Report pain reduced or controlled.  
Display relaxed facial expressions and body posture.

#### Pain Control NOC

Participate in activities and sleep and rest appropriately.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Pain Management: Acute NIC</b>	
<b>Independent</b>	

Be aware of types of pain that can occur with burns during the acute phase and with burn injury treatment:

- (1) *Acute pain* short-term intense pain that typically happens during a procedure like dressing changes or physical therapy; (2) *breakthrough pain* comes and goes despite pain medications, often due to wound healing, contractures, or repositioning; (3) *background pain* is burn-associated pain that is almost always present but is of lower intensity than the acute pain experienced during wound procedures; (4) *neuropathic pain* is caused by damage to and/or regeneration of nerve endings in the skin (Connor-Ballard, 2009; Drug Therapy Perspectives, 2001; Wiechman & Mason, 2016).

Assess client's pain, ongoing, noting location/character and intensity (using a standardized coding scale [e.g., numbers, pictures; pain thermometer]).

Identifying what client is experiencing at the moment helps in anticipating type of pain management needed at any given time. For example: Following the initial burn injury, there is a massive stimulation of nerve endings in the damaged skin, which is painful regardless of burn depth (inflammatory reactions causing extreme sensitivity to painful stimuli [*hyperalgesia*]). Manipulation of the hyperalgesic areas in the course of wound care exacerbates pain.

Pain is the common experience of all clients with burns—regardless of the cause, size, or depth of the burn—and the pain they experience can be among the worst known. Changes in location, character, and intensity of pain may indicate developing complications (e.g., limb ischemia) or herald improvement and return of nerve function and sensation. **P** Children with burn injuries, regardless of the severity of the burn, are often anxious and fearful in addition to being in physical pain, and each of these factors can exacerbate the other (Granger et al, 2009). Concerning analgesia needs in the burned child, Stafford and Curran stated “pediatric burns often require more

(continues on page 750)

**ACTIONS/INTERVENTIONS (continued)****RATIONALE (continued)**

Note nonverbal indicators of pain (e.g., changes in vital signs, grimacing, inconsolable crying, restlessness, trembling, or withdrawal from verbal communication or touch), especially in client who is unable to verbalize.	frequent and larger doses than typically recommended. It is not uncommon to repeat full doses until adequate pain control is achieved" (Stafford & Curran, 2010).
Cover wounds as soon as possible unless open-air exposure burn care method required.	Client (adult or child) may not be able to verbalize pain or pain characteristics due to age, developmental level, loss of consciousness or other cognitive issues, and/or type and severity of injuries.
Elevate burned extremities periodically.	Temperature changes and air movement can cause great pain to exposed nerve endings.
Wrap digits and extremities in position of function, avoiding flexed position of affected joints, using splints and footboards as necessary.	Elevation may be required initially to reduce edema formation; thereafter, changes in position and elevation reduce discomfort and risk of joint contractures.
Change position frequently and assist with active and passive range-of-motion (ROM) exercises, as indicated.	Position of function reduces deformities and contractures and promotes comfort. Although flexed position of injured joints may feel more comfortable, it can lead to flexion contractures.
Maintain comfortable environmental temperature; provide heat lamps and heat-retaining body coverings.	Movement and exercise reduce joint stiffness and muscle fatigue, but type of exercise depends on location and extent of injury.
Provide adequate pain medication and adjunctive medications, such as antianxiety drugs, before, during, or after a procedure, such as dressing changes and debridement.	Temperature regulation may be lost with major burns. External heat sources may be necessary to prevent chilling.
Encourage expression of feelings about pain.	The procedure may stimulate remaining nerve fibers, resulting in greater pain than was evident during the procedure. In some cases, conscious sedation for procedural pain may be needed to reduce severe physical and emotional distress associated with painful procedures.
Involve client in determining schedule for activities, treatments, and drug administration.	Verbalization allows outlet for emotions and may enhance coping mechanisms.
Explain procedures and provide frequent information as appropriate, especially during wound debridement.	Enhances client's sense of control and strengthens coping mechanisms.
Provide basic comfort measures—being present, gentle touch or massage, and frequent position changes.	Knowing what to expect provides opportunity for client to prepare self and enhances sense of control. Showing empathy and support can help alleviate pain and promote relaxation. Note: Burn injury and wound care often induces acute stress disorder, which heightens the pain experience. <b>P</b> Studies have shown that about 90% of both adults and children with burn injuries report at least one symptom of acute stress disorder right after the traumatic event, but only about 30% develop posttraumatic stress disorder (PTSD) (Gianoni-Pastor et al, 2016).
Instruct in and encourage use of stress management techniques, such as progressive relaxation, deep breathing, guided imagery, and visualization.	Promotes relaxation and reduces muscle tension and general fatigue. <b>P</b> Note: Studies on both adults and adolescents found that massaging burn injuries during the remodeling stage (after the acute stage of wound debridement) significantly reduced itching, as well as pain and anxiety (Field et al, 2000; Parlak Gurol et al, 2010).
Provide diversional activities appropriate for age and condition.	Refocuses attention, promotes relaxation, and enhances sense of control, which may enhance analgesia and/or reduce pharmacological dependency.
Promote uninterrupted sleep periods.	Helps refocus attention, lessening concentration on pain experience.
	Sleep deprivation can increase perception of pain and reduce coping abilities.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<p><b>Collaborative</b></p> <p>Administer analgesics (opioid and nonopioid) as indicated, such as morphine, fentanyl (Sublimaze, Ultiva), alfentanil (Alfenta), ketamine (Ketalar), hydrocodone (Vicodin, Hycodan), or oxycodone (OxyContin, Percocet)</p>	The burned client may require around-the-clock medication and dose titration. IV method is often used initially to maximize drug effect. Concerns of client addiction or doubts regarding degree of pain experienced are not valid during emergent and acute phases of care, but opioids should be decreased as soon as feasible and alternative methods for pain relief initiated. Note: Research is ongoing in search of new technologies for the nonpharmacologic management of severe pain, which may positively impact burn-related pain. For example, in a recent small investigational study, the use of virtual reality (VR) technology was found to be superior to standard controlled distraction therapy for the management of pain in hospitalized individuals (Tashjian et al, 2017).
<p>Provide and instruct in use of patient-controlled analgesia (PCA).</p>	PCA provides for timely drug administration, preventing fluctuations in intensity of pain, often at lower total dosage than would be given by conventional methods.

<p><b>NURSING DIAGNOSIS:</b> <b>risk for Infection</b></p> <p><b>Possibly Evidenced By</b> Alteration in skin integrity [destruction of skin barrier, traumatized tissues] Environmental exposure; invasive procedures Decreased in hemoglobin, leukopenia; suppressed inflammatory response</p> <p><b>Desired Outcomes/Evaluation Criteria—Client Will</b></p> <p><b>Burn Healing NOC</b> Achieve timely wound healing free of purulent exudate and be afebrile.</p>
---

ACTIONS/INTERVENTIONS	RATIONALE
<p><b>Infection Protection NIC</b></p> <p><i>Independent</i></p> <p>Be aware of client at high risk for development of infection.</p>	Infection is the most common cause of morbidity and mortality in the burn-injured population, with almost 61% of deaths being caused by infection (Fonseca & Hespenthal, 2016).
<p>Examine wounds daily; document and report changes in appearance, odor, or quantity of drainage.</p>	Identifies presence of granulation tissue indicating healing and provides for early detection of burn-wound infection. Infection in a partial-thickness burn may cause conversion of burn to full-thickness injury. Note: Early signs may not be obvious (changes are primarily in numbers of bacteria colonization in the wound). Cellulitis manifests as erythema, induration, warmth, and tenderness in the tissue surrounding the burn wound and, occasionally, the development of sepsis (Fonseca & Hespenthal, 2016).
<p>Emphasize and model good handwashing technique for all individuals coming in contact with client.</p>	Prevents cross-contamination from one wound area to another and reduces risk of healthcare-acquired infection.
<p>Implement appropriate isolation techniques, as indicated.</p>	Dependent on type and extent of wounds and the choice of wound treatment (e.g., open versus closed); isolation may range from simple wound and skin to complete or reverse to reduce risk of cross-contamination and exposure to multiple bacterial flora.
<p>Use gowns, gloves, masks, and strict aseptic technique during direct wound care and provide sterile or freshly laundered bed linens and gowns.</p>	Prevents exposure to infectious organisms.

(continues on page 752)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Monitor and limit visitors, if necessary. Explain isolation procedure to visitors, if used. Supervise visitor adherence to protocol as indicated.	Prevents cross-contamination from visitors. Concern for risk of infection should be balanced against client's need for family support and socialization.
<b>Wound Care: Burns NIC</b> Shave/clip all hair from around burned areas, (where indicated) to include a 1-inch border (excluding eyebrows). Shave facial hair (men) and shampoo head daily.	Hair is a good medium for bacterial growth; however, eyebrows act as a protective barrier for the eyes. Regular shampooing decreases bacterial fallout into burned areas.
Examine unburned areas, such as groin, neck creases, and mucous membranes, and note onset of vaginal discharge in women.	Opportunistic infections (e.g., yeast) frequently occur because of depression of the immune system and/or proliferation of normal body flora during systemic antibiotic therapy.
Provide special care for eyes, for example, use eye covers and tear formulas as appropriate.	Eyes may be swollen shut and/or become infected by drainage from surrounding burns. If lids are burned, eye covers may be needed to prevent corneal damage.
Prevent skin-to-skin surface contact—wrap each burned finger or toe separately; do not allow burned ear to touch scalp.	Prevents adherence to the surface that it may be touching and encourages proper healing. Note: Ear cartilage has limited circulation and is prone to pressure necrosis.
Monitor vital signs for fever and increased respiratory rate and depth in association with changes in sensorium, presence of diarrhea, decreased platelet count, and hyperglycemia with glycosuria.	Indicators of sepsis—often occurring with full-thickness burn—requiring prompt evaluation and intervention. Note: Changes in sensorium, bowel habits, and respiratory rate usually precede fever and alteration of laboratory studies.
<b>Collaborative</b> Remove dressings and cleanse burned areas in a hydrotherapy or whirlpool tub or in a shower stall with handheld showerhead. Maintain temperature of water at 100°F (37.8°C). Wash areas with a mild cleansing agent or surgical soap.	Water softens and aids in removal of dressings, slough layer of dead skin or tissue, and dry scabs or eschar. Sources vary as to whether bath or shower is best. Bath has advantage of water providing support for exercising extremities but may promote cross-contamination of wounds. Showering enhances wound inspection and prevents contamination from floating debris.
Excise and cover burn wounds quickly.	Early excision is known to reduce scarring and risk of infection, thereby facilitating healing.
Debride necrotic and loose tissue, including ruptured blisters, with scissors and forceps. Do not disturb intact blisters if they are smaller than 1 to 2 cm, do not interfere with joint function, and do not appear infected.	Promotes healing and prevents autocontamination. Small, intact blisters help protect skin and increase rate of reepithelialization unless the burn injury is the result of chemicals, in which case fluid contained in blisters may continue to cause tissue destruction.
Photograph wound initially and at periodic intervals.	Provides baseline and documentation of healing process.
<b>Infection Protection NIC</b> Maintain aseptic technique when inserting invasive lines and tubes (e.g., Foley catheter). Remove invasive devices as early as possible.	Reduces access for healthcare-acquired infections related to invasive procedures and devices. Note: The clinical signs of sepsis in the burned client are subtle and are easily missed until septic shock is present. Client with burns has lost the primary barrier to infectious invasion (skin). In addition, the client with extensive burns develops a profound hypermetabolic response that heightens the risk for sepsis and multiple-organ dysfunction syndrome (MODS) as long as the wounds are open (Greenhalgh, 2017).
Administer topical antimicrobial agents, as indicated, for example:	The following agents help control bacterial growth and prevent drying of wound, which can cause further tissue destruction (Fonsesca & Hospenthal, 2016).

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Chlorhexidine (Hibiclens) topical wash	Effective, safe, and reliable against gram-positive and gram-negative organisms, facultative anaerobes (grows with or without oxygen), aerobes (requires oxygen for growth), and yeast.
Silver sulfadiazine (Silvadene, Flammazine)	Still the most common topical antibiotic used in burn care, Silvadene is useful in the prevention of infections from second- or third-degree burns. It has bactericidal activity against many gram-positive and gram-negative bacteria, including yeast.
Mafenide (Sulfamylon) solution or mafenide HCl cream	Antibiotic of choice with confirmed invasive burn wound infection that does not respond to Silvadene. Useful against gram-negative and gram-positive organisms and some fungal species. The solution is painless; however, the cream causes burning or pain on application and for 30 minutes thereafter. Can cause rash and is contraindicated in metabolic acidosis.
Silver-coated dressings (e.g., Acticoat, Aquacel Ag)	Nonadherent antimicrobial dressings that stay on the wound for up to 7 days, delivering a low concentration of nanocrystalline silver, with the added benefit of reduced pain with application or removal. Available in knitted flexible fabric useful for circumferential burn care (Fong et al, 2005).
Silver nitrate	Effective against <i>Staphylococcus aureus</i> , <i>Escherichia coli</i> , and <i>Pseudomonas aeruginosa</i> but has poor eschar penetration, is painful, and may cause electrolyte imbalance. Dressings must be constantly saturated. Product stains skin and other surfaces black.
Poloxamer 188 (Primaderm)	This gel is effective against gram-positive organisms, does not interfere with reepithelialization, and is generally used for tar and asphalt-based residues, other imbedded materials, and for superficial and facial burns.
Hydrogels, such as Aquasite sheet dressings	Useful for partial- and full-thickness burns, in rehydrating dry wound beds, and promoting autolytic debridement. Because of the moisture provided to the wound from the hydrogel dressing, healing phases (e.g., removal of dead tissue, granulation, and epidermis repair) are simplified. In addition, the cool sensation provided by the hydrogel to the wound offers relief from pain.
Administer other medications, as appropriate, for example:	
Subeschar clysis or systemic antibiotics	Systemic antibiotics are given to control general infections identified by culture and sensitivity. Subeschar clysis has been found effective against pathogens in granulated tissues at the line of demarcation between viable and nonviable tissue, reducing risk of sepsis.
Tetanus toxoid or clostridial antitoxin, as appropriate.	Tissue destruction and altered defense mechanisms increase risk of developing tetanus or gas gangrene, especially in deep burns such as those caused by electricity.
Place IV and invasive lines in nonburned area.	Decreased risk of infection at insertion site with possibility of progression to septicemia.
Obtain routine cultures and sensitivities of wounds and drainage.	Allows early recognition and specific treatment of wound infection.
Assist with excisional biopsies when infection is suspected.	Bacteria can colonize the wound surface without invading the underlying tissue; therefore, biopsies may be obtained for diagnosing infection.

## NURSING DIAGNOSIS: risk for peripheral Neurovascular Dysfunction

### Possibly Evidenced By

Burn injury; immobilization  
Trauma; fractures  
Mechanical compression (e.g., circumferential burns/edema of extremities)

### Desired Outcomes/Evaluation Criteria—Client Will

#### Tissue Perfusion: Peripheral NOC

Maintain palpable peripheral pulses of equal quality and strength; good capillary refill, free of numbness or paresthesia.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Circulatory Care: Venous [or] Arterial NIC</b>	
<b>Independent</b>	
Assess color, sensation, movement, capillary refill, and peripheral pulses via Doppler on extremities with circumferential burns.	Edema formation can readily compress blood vessels, thereby impeding circulation and increasing venous stasis and edema.
Compare findings between limbs if burn is unilateral.	Comparisons with unaffected limbs aid in differentiating localized versus systemic problems (e.g., hypovolemia and decreased cardiac output).
Elevate affected extremities, as appropriate. Remove jewelry or arm band. Avoid taping around a burned extremity or digit.	Promotes systemic circulation and venous return and may reduce edema or other deleterious effects of constriction of edematous tissues. Note: Prolonged elevation can impair arterial perfusion if BP falls or tissue pressures rise excessively.
Obtain BP in unburned extremity when possible. Remove BP cuff after each reading, as indicated.	If BP readings must be obtained on an injured extremity, leaving the cuff in place may increase edema formation, reduce perfusion, and convert partial-thickness burn to a more serious injury.
Investigate reports of deep, throbbing ache and numbness.	Indicators of decreased perfusion and/or increased pressure within enclosed space, such as may occur with a circumferential burn of an extremity (compartment syndrome).
Encourage active ROM exercises of unaffected body parts.	Promotes local and systemic circulation.
Investigate irregular pulses.	Cardiac dysrhythmias can occur as a result of electrolyte shifts, electrical injury, or release of myocardial depressant factor, compromising cardiac output and tissue perfusion.
<b>Collaborative</b>	
Maintain fluid replacement per protocol. (Refer to ND: risk for deficient Fluid Volume.)	Maximizes circulating volume and tissue perfusion.
Monitor electrolytes, especially sodium, potassium, and calcium. Administer replacement therapy, as indicated.	Losses or shifts of these electrolytes affect cellular membrane potential and excitability, thereby altering myocardial conductivity, potentiating risk of dysrhythmias, and reducing cardiac output and tissue perfusion.
Avoid use of intramuscular (IM) and subcutaneous (SC) injections.	Altered tissue perfusion and edema formation impair drug absorption. Injections into potential donor sites may render them unusable because of hematoma formation.
Measure intracompartmental pressures as indicated. (Refer to CP: Fractures; ND: risk for peripheral Neurovascular Dysfunction.)	Ischemic myositis may develop because of decreased perfusion.
Assist with or prepare for escharotomy or fasciotomy, as indicated.	Enhances circulation by relieving constriction caused by rigid, nonviable tissue (eschar) or edema formation.

**NURSING DIAGNOSIS:** **imbalanced Nutrition: less than body requirements****May Be Related To**

Inability to ingest food [to meet needs] (e.g., hypermetabolic state; protein catabolism)

**Possibly Evidenced By**

Bodyweight 20% or more below ideal weight range; insufficient muscle tone

Food intake less than recommended daily allowance; insufficient interest in food; food aversion; satiety immediately after ingesting food

[Development of negative nitrogen balance]

**Desired Outcomes/Evaluation Criteria—Client Will****Nutritional Status NOC**

Demonstrate nutritional intake adequate to meet metabolic needs as evidenced by stable weight and muscle mass measurements, positive nitrogen balance, and tissue regeneration.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Nutrition Therapy NIC</b>	
<b>Independent</b>	
Auscultate bowel sounds, noting hypoactive or absent sounds.	Ileus is often associated with postburn period but usually subsides within 36 to 48 hours, at which time oral or enteral feedings can be initiated.
Determine food and calorie count. Weigh daily. Reassess percentage of open body surface area and wounds weekly.	Appropriate guides to proper caloric intake include 25 kcal/kg body weight, plus 40 kcal per percentage of TBSA burn in the adult. As burn wound heals, energy needs are reevaluated to calculate prescribed dietary formulas and appropriate adjustments are made.
Monitor muscle mass and subcutaneous fat, as indicated.	Indirect calorimetry, if available, may be useful in more accurately estimating body reserves and losses and effectiveness of therapy.
Provide small, frequent meals and snacks.	Helps prevent gastric distention or discomfort and may enhance intake.
Encourage client to view diet as a treatment and to make food and beverage choices high in calories and protein.	Calories and proteins are needed to meet metabolic needs and promote wound healing.
Ascertain food likes and dislikes. Encourage SO to bring food from home, as appropriate.	Provides client/SO sense of control; enhances participation in care and may improve intake.
Encourage client to sit up for meals and visit with others.	Sitting helps prevent aspiration and aids in proper digestion of food. Socialization promotes relaxation and may enhance intake.
Provide oral hygiene before meals.	Clean mouth and clear palate enhances taste and helps promote a good appetite.
Perform fingerstick glucose and urine testing, as indicated.	Monitors for development of hyperglycemia related to hormonal changes and demands or use of hyperalimentation to meet caloric needs.
<b>Collaborative</b>	
Refer to dietitian or nutritional support team.	Useful in establishing individual nutritional needs based on weight and body surface area of injury and identifying appropriate routes. Note: Hypermetabolic state can increase caloric needs as much as 50% to 60% higher than normal proportional to the severity of injury (Rousseau et al, 2013).
Provide diet high in calories and protein with trace elements and vitamin supplements.	Calories approximating 25 kcal/kg/d, protein up to 2 g/kg/d, and vitamins are needed to meet increased metabolic needs, maintain weight, and encourage tissue regeneration. Energy from fat should be <35% of total energy during early acute phase to minimize the susceptibility to infection. Micronutrients that might be required include zinc, copper and selenium, as well as vitamins B <sub>1</sub> , C, D, and E (Rousseau et al, 2013).

(continues on page 756)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Insert and maintain small feeding tube for enteral feedings and supplements, if needed.	Provides continuous or supplemental feedings when client is unable to consume total daily calorie requirements orally. Note: Research supports use of early intragastric feedings as soon after admission as possible because delayed enteral feeding longer than 18 hours postinjury results in a high rate of gastroparesis and need for IV nutrition. Continuous tube feeding during the night increases calorie intake without decreasing appetite and oral intake during the day.
Administer parenteral nutritional solutions containing vitamins and minerals, as indicated.	If enteral feeding is not possible, total parenteral nutrition (TPN) may be initiated to meet metabolic needs in the presence of severe burn complications or esophageal or gastric injuries. (Refer to CP: Total Nutritional Support: Parenteral/Enteral Feeding.)
Monitor laboratory studies, such as serum albumin or prealbumin, glucose, electrolytes, magnesium, BUN/Cr, calcium, inorganic phosphorus, transaminase, and triglycerides.	Indicators of nutritional needs and adequacy of diet and therapy.
Administer insulin, as indicated.	Elevated serum glucose levels may develop because of stress response to injury, high caloric intake, and pancreatic fatigue.

### NURSING DIAGNOSIS: impaired physical Mobility

#### May Be Related To

Pain; anxiety  
Decreased muscle strength; joint stiffness [contractures]  
Reluctance to initiate movement; prescribed movement restrictions, limb immobilization  
Decrease in endurance

#### Possibly Evidenced By

Decrease in range of motion; decrease in fine motor skills  
Difficulty turning  
Alteration in gait; postural instability

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Immobility Consequences: Physiological NOC

Maintain position of function as evidenced by absence of contractures.  
Maintain or increase strength and function of affected and/or compensatory body part.

##### Self-Care: Activities of Daily Living (ADLs) NOC

Demonstrate techniques and behaviors that enable resumption of activities.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Bedrest Care NIC</b> <i>Independent</i>	Aids in identifying potential issues (e.g., loss of body part or function, contractures) and points toward rehabilitation measures needed immediately to minimize deformities.
Maintain proper body alignment with supports, splints, specialty mattress, and so on. Ascertain that splints and supports are correct in type, size, and placement. Inspect all splints regularly for evidence of poor fit or pressure injury.	Promotes functional positioning of body and extremities to limit development/severity of contractures.
Note circulation, motion, and sensation of digits frequently.	Edema may compromise circulation to extremities, potentiating tissue necrosis and development of contractures.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Initiate the rehabilitative phase on admission.	To attain the goal of optimal long-term function, rehabilitation must begin at the outset of burn care. Treatment goals and strategies vary, depending on the client's burn (and other injuries), stage of burn treatment, age, and comorbidities.
Perform/assist with ROM exercises consistently, initially passive, progressing to active.	In the seriously ill burned client, goals are to limit loss of range of motion (ROM), reduce edema, and prevent contractures.
Medicate for pain before activity or exercises.	Reduces pain and tissue stiffness and tension, enabling client to be more active and facilitating therapy.
Schedule treatments and care activities to provide periods of uninterrupted rest.	Increases client's strength and tolerance for activity.
Encourage family/SO support and assistance with ROM exercises.	Enables family/SO to be active in client care and provides more constant and consistent therapy.
<b>Self-Care Assistance NIC</b>	
Incorporate ADLs with physical therapy, hydrotherapy, and nursing care.	Combining activities produces improved results by enhancing effects of each.
Encourage client participation in all activities as individually able.	Promotes independence, enhances self-esteem, and facilitates recovery process.
Instruct and assist with mobility aids, such as a cane, walker, or crutches, as appropriate.	Promotes safe ambulation.
<b>Bed Rest Care NIC</b>	
<i>Collaborative</i>	
Collaborate with rehabilitation, physical, and occupational therapists.	Normally members of the burn team, these specialists provide integrated activity and exercise programs and specific assistive devices based on individual needs.
Provide foam or flotation mattress or kinetic therapy bed, as indicated.	Prevents prolonged pressure on tissues, reducing potential for tissue ischemia, necrosis, and decubitus ulcer formation.
Maintain pressure garment when used.	Hypertrophic scarring can develop around grafted areas or at the site of deep partial-thickness wounds. Pressure dressings minimize scar tissue by keeping it flat, soft, and pliable, enhancing movement.

### NURSING DIAGNOSIS: impaired Skin Integrity [grafts/donor site]

#### May Be Related To

[Burn injury]

#### Possibly Evidenced By

Disruption of skin surface/layers

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Burn Healing NOC

Demonstrate tissue granulation.

Achieve timely healing of burn wounds.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Skin Care: Graft/Donor Site NIC</b>	
<i>Independent</i>	
<b>Preoperative</b>	
Assess and document size, color, depth of wound, noting necrotic tissue and condition of surrounding skin.	Provides baseline information about need for skin grafting and possible clues about circulation in area to support graft.

(continues on page 758)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Provide appropriate burn care and infection control measures. (Refer to ND: risk for Infection.)	Prepares tissues for grafting and reduces risk of infection and graft failure.
<b>Collaborative</b> Administer topical wound debridement ointment, as indicated, for example, enzymatic products—collagenase ointment (Santyl) and papain (Accuzyme).	Early debridement of burn eschar is beneficial to wound healing, and some treatment centers suggest use of these products to promote healing. However, despite theoretical advantage, enzymatic debridement results have been highly variable.
<b>Independent</b> <b>Postoperative</b>	
Elevate grafted area, if possible and appropriate.	Reduces swelling and limits risk of graft separation.
Maintain desired position and immobility of area when indicated.	Movement of tissue under graft can dislodge it, interfering with optimal healing.
Maintain dressings (mesh, petroleum, nonadhesive) over newly grafted area and/or donor site, as indicated.	Areas may be covered by translucent, nonreactive surface material between graft and outer dressing to eliminate shearing of new epithelium to protect healing tissue. The donor site is usually covered for 4 to 24 hours, then bulky dressings are removed and fine mesh gauze is left in place.
Keep skin free from pressure.	Promotes circulation and prevents ischemia, necrosis, and graft failure.
Evaluate color of grafted and donor site(s); note signs of healing.	Evaluates effectiveness of circulation and identifies developing complications.
<b>Collaborative</b> Maintain prescribed wound covering (skin substitutes) as indicated, for example: <b>alginates</b> (e.g., Aquacel, Coloplast), <b>antimicrobials</b> (e.g., Acticoat, Silverlon), <b>collagens</b> (e.g., Fibracol, Puracol), <b>hydrocolloids</b> (e.g., Duoderm, Granuflex, Tegaderm), <b>hydrogels</b> (e.g., Dermagel, Silva-Sorb, Skintegrity), and <b>polyurethane foams</b> (e.g., Allevyn, Lyofoam) (Rowan et al, 2015).	The selection of an appropriate dressing depends on several factors (e.g., depth of burn, condition of the wound bed, wound location, desired moisture retention and drainage, required frequency of dressing changes, and cost). While many factors must be considered in dressing selection, the goals in selecting the most appropriate dressing should include (1) providing protection from contamination (bacterial or otherwise) and from physical damage, (2) allowing gas exchange and moisture retention, and (3) providing comfort to enhance functional recovery (Broussard & Powers, 2013).
Human fibroblast-derived temporary skin substitute (TransCyte)	Useful for eschar-free, partial-thickness burns awaiting autografts because it can remain in place for longer periods of time and is permeable to topical antimicrobial agents.
Prepare for/assist with surgical grafting or biological dressings, such as the following:	
Homograft (allograft)	Skin grafts obtained from living persons or cadavers are used as a temporary covering for extensive burns until individual's own skin is ready for grafting (test graft) to cover excised wounds immediately after escharotomy or to protect granulation tissue.
Heterograft (xenograft, porcine)	Skin grafts may be carried out with animal skin for the same purposes as homografts or to cover meshed autografts.
Cultured epithelial autograft (CEA) (e.g., Epicel)	Skin graft obtained from uninjured part of client's own skin and prepared in a laboratory. Note: While CEA can provide coverage of a large surface area defect using a small amount of donor tissue, this type of skin substitute has been associated with high rates of infection and graft loss, confirming the importance of the dermal layer in skin grafting. Cultured skin substitute (CSS) is composed of a CEA combined with a cultured autologous dermal layer; therefore, it addresses both the dermal and epidermal skin layers.

**NURSING DIAGNOSIS:** **risk for Post-Trauma Syndrome**
**Possibly Evidenced By**

Perceives event as traumatic; serious injury to self  
Survivor role  
Duration of traumatic event; exposure to disaster

**Desired Outcomes/Evaluation Criteria—Client Will**
**Personal Resiliency NOC**

Identify healthy ways to deal with feelings.  
Verbalize absence of severe anxiety, or reduced anxiety or fear when memories occur.  
Demonstrate ability to deal with emotional reactions in an individually appropriate manner.  
Demonstrate effective problem-solving skills.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Crisis Intervention NIC</b>	
<i>Independent</i>	
Assess meaning of loss or change to client and SO, including future expectations and impact of cultural and religious beliefs.	Traumatic episode results in sudden, unanticipated changes, creating feelings of grief over actual or perceived losses. This necessitates support to work through to optimal resolution.
Acknowledge and accept expression of feelings of frustration, dependency, anger, grief, and hostility. Note withdrawn behavior and use of denial.	Acceptance of these feelings as a normal response to what has occurred facilitates resolution. It is not helpful or possible to push client before he or she is ready to deal with the situation. Denial may be prolonged and be an adaptive mechanism because client is not ready to cope with personal problems.
Provide frequent explanations and information about care procedures. Repeat information as needed or desired.	Knowing what to expect usually reduces anxiety, clarifies misconceptions, and promotes cooperation. Note: Because of the shock of the initial trauma, many people do not recall information provided during that time.
Demonstrate willingness to listen and talk to client when free of painful procedures.	Helps client and SO know that support is available and that healthcare provider is interested in the person, not just care of the burn.
Involve client and SO in decision-making process whenever possible. Provide time for questioning and repetition of proposed treatments.	Promotes sense of control and cooperation, decreasing feelings of helplessness or hopelessness.
Assess mental status, including mood and affect, comprehension of events, and content of thoughts, such as illusions or manifestations of terror or panic.	Initially, client may use denial and repression to reduce and filter information that might be overwhelming. Some clients display calm manner and alert mental status, representing dissociation from reality, which is also a protective mechanism.
Provide constant and consistent orientation. Explain to client what happened. Provide opportunity for questions and give open and honest answers.	Helps client stay in touch with surroundings and reality. Adjustment to the impact of the trauma and grief over losses and disfigurement can easily lead to clinical depression, psychosis, and PTSD. Compassionate statements reflecting the reality of the situation can help client and SO acknowledge the reality and begin to deal with what has happened.
Investigate changes in mentation and presence of hypervigilance, hallucinations, sleep disturbances (e.g., nightmares), agitation or apathy, disorientation, and labile affect, all of which may vary from moment to moment.	Indicators of acute stress response or delirium state in which client is literally fighting for life. Although cause can be psychologically based, pathological life-threatening causes, such as shock, sepsis, or hypoxia, must be ruled out.
Set limits on maladaptive behavior (e.g., manipulative or aggressive). Maintain nonjudgmental attitude while giving care, and help client identify positive behaviors that will aid in recovery.	Client and SO tend to deal with this crisis in the same way in which they have dealt with problems in the past. Staff may find it difficult and frustrating to handle behavior that is disrupting and not helpful to recuperation but should realize that the behavior is usually directed toward the situation and not the care provider.

(continues on page 760)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Encourage client to talk about the burn circumstances when ready.	Client may need to tell the story of what happened over and over to make some sense out of a terrifying situation.
Identify previous methods of coping with and handling stressful situations.	Past successful behavior can be used to assist in dealing with the present situation.
Create a restful environment; use guided imagery and relaxation exercises.	Clients experience severe anxiety associated with burn trauma and treatment. These interventions are soothing and helpful for positive outcomes.
Assist the family to express their feelings of grief and guilt.	The family may initially be most concerned about client's dying and/or feel guilty, believing that in some way they could have prevented the incident.
Be empathetic and nonjudgmental in dealing with client and family.	Family relationships are disrupted; financial, lifestyle, and role changes make this a difficult time for those involved with client, and they may react in many different ways.
Encourage family/SO to visit and discuss family happenings. Remind client of past and future events.	Maintains contact with a familiar reality, creating a sense of attachment and continuity of life.
<b>Collaborative</b>	
Involve entire burn team in care from admission to discharge, including social worker and psychiatric resources.	Provides a wide support system and promotes continuity of care and coordination of activities.
Administer mild sedation, as indicated, for example, lorazepam (Ativan), alprazolam (Xanax).	Antianxiety medications may be necessary for a short period of time until client is more physically stable and internal locus of control is regained.

**NURSING DIAGNOSIS:** **deficient Knowledge regarding condition, prognosis, treatment, self-care, and discharge needs.**

**May Be Related To**

Insufficient information; insufficient knowledge of resources  
Misinformation presented by others  
Alteration in cognitive function/memory; insufficient interest in learning

**Possibly Evidenced By**

Insufficient knowledge  
Inaccurate follow-through of instructions; development of preventable complications  
Inappropriate behavior

**Desired Outcomes/Evaluation Criteria—Client Will**

**Knowledge: Disease Process NOC**

Verbalize understanding of condition, prognosis, and potential complications.

**Knowledge: Treatment Regimen NOC**

Verbalize understanding of therapeutic needs and treatment plan(s).  
Correctly perform necessary procedures and explain reasons for actions.  
Initiate necessary lifestyle changes and participate in treatment and rehabilitation regimen.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Teaching: Disease Process NIC</b>	
<b>Independent</b>	
Review condition, prognosis, and future expectations.	Provides knowledge base from which client can make informed choices.
Discuss client's expectations of returning home, to work, and to normal activities. Role-play social situations of concern to client.	Client frequently has a difficult and prolonged adjustment after discharge. Problems, such as sleep disturbances, nightmares, reliving the accident, difficulty with resumption of social interactions or intimacy and sexual activity, and emotional lability, often occur and can interfere with successful adjustment to resuming normal life.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Review and have client and SO demonstrate proper burn, skin graft, and wound care techniques. Identify appropriate sources for outpatient care and supplies.	Promotes competent self-care after discharge, enhancing independence.
Discuss skin care, such as scar massage and use of perfume-free moisturizers (e.g., Vaseline Intensive Care, Eucerin), sunscreens, and anti-itching medications (e.g., diphenhydramine [Benadryl], hydroxyzine [Atarax]).	Itching, blistering, and sensitivity of healing wounds and graft sites can be expected for an extended time, and injury can occur because of the lack of natural lubrication and fragility of the new tissue. Note: Sunblock may be required for life because of potential for hyperpigmentation.
Explain scarring process and necessity for and proper use of silicone gel sheeting, static splint, or pressure garments when used.	Helps minimize and treat hypertrophic scarring and contracture formation. Consistent use of the pressure garment over a long period can reduce the need for reconstructive surgery to release contractures and remove scars. <b>P</b> Note: Remind parent that child wearing pressure garment should be evaluated periodically for proper fit due to growth.
Recommend contact with survivor support person or group for client and SO, such as Survivors Offering Assistance in Recovery (SOAR). Give information about how SO can be helpful to client.	Provides a connection with a supporter who has experienced a burn injury. Talking with someone who has been directly impacted by a burn or by tissue injury can be reassuring, because he or she has had similar experiences and is familiar with what lies ahead.
Encourage continuation of prescribed exercise program and scheduled rest periods.	Maintains mobility, reduces complications, and prevents fatigue, facilitating recovery process.
Identify specific limitations of activity as individually appropriate.	Imposed restrictions depend on the severity and location of the injury and the stage of healing.
Emphasize importance of sustained intake of high-protein and high-calorie meals and snacks.	Optimal nutrition enhances tissue regeneration and general feeling of well-being. Note: Client often needs to increase caloric intake to meet calorie and protein needs for healing.
Review medications, including purpose, dosage, route, and expected or reportable side effects.	Reiteration allows opportunity for client to ask questions and be sure understanding is accurate.
Advise client and SO of potential for exhaustion, boredom, emotional lability, and adjustment problems. Provide information about possibility of discussion as well as interaction with appropriate professional counselors.	Provides perspective to some of the problems that client/SO may encounter and aids awareness that assistance is available when necessary.
Identify signs and symptoms requiring medical evaluation— inflammation, increase or changes in wound drainage, fever, chills, changes in pain characteristics, or loss of mobility or function.	Early detection of developing complications (e.g., infection, delayed healing) may prevent progression to more serious or life-threatening situations.
Emphasize necessity and importance of follow-up care and rehabilitation program including physical/occupational therapy and vocational counseling.	Long-term support with continual reevaluation and changes in therapy is required to regain and maintain independence and achieve optimal recovery.
Provide phone number for contact person.	Provides easy access to treatment team to reinforce teaching, clarify misconceptions, and reduce potential for complications.
Identify community resources, such as skin and wound care professionals and crisis centers, recovery groups, and mental health, American Red Cross, visiting nurse, Ambli-Cab, and homemaker service.	Facilitates transition to home, provides assistance with meeting individual needs, and supports independence.

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

- **ineffective Coping**—situational crisis, severe/chronic pain; inadequate level of confidence in ability to cope
- **disturbed Body Image**—alteration in body structure, function; fear of rejection by others

(continues on page 762)

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities) (continued)

- **risk for Disuse Syndrome**—severe pain, prescribed immobilization or restrictive therapies
- **risk for situational low Self-Esteem**—functional impairment; loss; disturbed body image
- **ineffective Health Management**—complexity of therapeutic regimen; economic difficulties; added demands made on individual/family; social support deficits
- **Post-Trauma Syndrome**—events outside the range of usual human experience; serious injury to self

## WOUND CARE: COMPLICATED OR CHRONIC

**I. Pathophysiology**—destruction of various layers of the integument as the result of purposeful action (surgical procedure), disease processes, impaired circulation, or incidental trauma (pressure, shearing forces)

**II. Types of Wounds**

- a. Surgical: These are surgical wounds that failed to heal or have dehisced.
- b. Traumatic: unintentional or intentional
- c. Foot ulcers: Most often occurs in diabetics and are associated with polyneuropathy and injury. It is estimated that 2% to 5% of persons with diabetes will develop foot ulcers each year (Maydick & Acee, 2016; Rowe, 2017).  
*Note:* These wounds may be classified with Meggit-Wagner Ulcer Classification (grades 0–5) (see Glossary below).
- d. Leg ulcers: Venous stasis causes about 80% of lower-extremity ulcers (Kolluri, 2014) but are also associated with peripheral arterial disease (PAD) and sickle cell disease.
- e. Pressure ulcers/injury (also called decubitus ulcers): occur because of prolonged ischemia-producing external pressure, usually to a soft tissue region overlying a bony prominence. Shearing forces, exposure to constant moisture, and heat buildup also are major contributing factors.
- f. Irritant dermatitis: urinary or fecal incontinence, leaking tubes or drains
- g. SCALE (see Glossary) ulcers: develop most commonly on sacrum or coccyx as skin fails as a part of the dying process and blood is shunted away from the skin to vital organs.

**III. Etiology** (Baley, 2013; Daley & Bhat, 2017; Kolluri, 2014; Rowe, 2017)

- a. Neuropathy, such as occurs with diabetes, spinal cord injury, cerebral palsy, Hansen's disease
- b. Ischemia associated with atherosclerosis, microangiopathy (such as occurs with diabetes), arterial or venous insufficiency, any form of peripheral vascular disease
- c. Infection: potentiates collagen lysis; bacterial contamination, a susceptible host and wound environment is required
- d. Peripheral edema: due to elevated venous pressure such as occurs with varicose veins or deep vein thrombosis (DVT); cardiopulmonary conditions (e.g., congestive heart failure); untreated lymphedema
- e. Direct pressure, such as occurs with immobility, paralysis, poor mobility occurring due to advanced age, dementia, or terminal illness
- f. Medical device-related pressure injuries result from the use of devices designed and applied for diagnostic or therapeu-

tic purposes.  **Note:** Medical devices are associated with 50% of pressure ulcers in pediatric clients (Freundlich, 2017).

- g. Miscellaneous direct or associated causes: connective tissue disorders, vasculitis, arteriovenous malformations, pharmacological agents (e.g., corticosteroids, hydroxyurea), neoplasms/malignancy, radiation, osteomyelitis, poor nutritional status, smoking

**IV. Staging** (Redefined by National Pressure Ulcer Advisory Panel [NPUAP], 2016)

- a. Stage I: intact skin, nonblanchable redness in localized area (may be difficult to detect in dark-skinned person)
- b. Stage II: partial-thickness loss of skin with exposed dermis. The wound bed is viable, pink or red, moist, and may also present as an intact or ruptured serum-filled blister.
- c. Stage III: full-thickness skin loss. Adipose is visible in the ulcer; granulation tissue and epibole (see Glossary) are often present. Slough and/or eschar may be visible. Undermining and tunneling may occur.
- d. Stage IV: full-thickness skin and tissue loss, with exposed fascia, muscle, or bone in ulcer. Slough and/or eschar may be visible. Epibole, undermining, and/or tunneling often occur.
- e. Unstageable: full-thickness tissue loss in which the base of the ulcer is covered in the wound bed. Full-thickness skin and tissue loss in which the extent of tissue damage within the ulcer cannot be confirmed because it is obscured by slough or eschar. If slough or eschar is removed, a stage 3 or stage 4 pressure injury will be revealed.
- f. Deep tissue pressure injury (DTPI): intact or nonintact skin with localized area of persistent nonblanchable deep red, maroon, or purple discoloration or epidermal separation revealing a dark wound bed or blood-filled blister. Pain and temperature change often precede skin color changes.

**V. Statistics**

- a. Morbidity: Infection is the most common major complication of pressure injuries. Chronic wounds have a significant impact on health and quality of life, causing pain, loss of function and mobility, depression, distress and anxiety, embarrassment and social isolation, financial burden, prolonged hospital stays, and chronic morbidity (Järbrink et al, 2016; MacDonald, 2009).
- b. Mortality: A study published in 2008 (using 2006 data) reported that in-hospital mortality was higher for pressure ulcer-related hospitalizations than hospitalizations for other diagnoses (and especially among those with a *secondary* diagnosis of pressure ulcers). In-hospital death

## G L O S S A R Y

- Approximated:** Wound edges to a surgical incision are either sutured or stapled so that edges touch, forming a thin line.
- Dehisced:** A break in the continuity of the surgical wound.
- Deep tissue injury:** Persistent localized area of nonblanchable deep red, maroon, or purple discoloration of skin that is either intact or a blood-filled blister. This injury results from intense and/or prolonged pressure and shear forces at the bone-muscle interface. *Note:* This term is not used to describe vascular, traumatic, neuropathic, or dermatologic conditions (Freundlich, 2017).
- Epibole (rolled wound edges):** Results when the upper epidermal cells roll down over the lower epidermal cells and migrate down the sides of the wound instead of across the wound. The body thinks the wound is healed, causing cessation of the healing process.
- Eschar:** Hard crust or scab that forms over the wound, is typically dark brown or black, and must be removed in order for wound to begin healing.
- Meggitt-Wagner Ulcer Classification:** A specific classification system for diabetic foot ulcers; however, it does not capture the depth of the wound (grade 0: preulceration lesion, healed ulcer, or presence of bony deformity; grade 1: superficial ulcer; grade 2: ulcer penetrates through subcutaneous tissue and may have exposed bone, tendon, muscle, etc.; grade 3: presence of osteitis, abscess, or osteomyelitis; grade 4: gangrene of a digit; grade 5: gangrene of the foot).
- Medical device-related pressure injury:** Results from the use of devices designed and applied for diagnostic or therapeutic purposes. The pressure injury generally conforms to the pattern or shape of the device. The injury should be staged using the staging system.
- Mucosal membrane pressure injury:** Found on mucous membranes with a history of a medical device in use at the location of the injury (e.g., nasogastric tube, endotracheal [ET] tube, splints, braces). Due to the anatomy of the tissue, these ulcers cannot be staged.
- Necrosis (or necrotic tissue):** Death of cells, usually within a localized area of the body, as from an interruption of the blood supply to that part.

## CARE SETTINGS

All care settings.

individual patient care ranges from \$20,900 to \$151,700 per pressure ulcer (AHRQ, 2014). A recent study of diabetics with and without diabetic foot ulcers (DFUs) revealed that DFUs impose a substantial burden on public and private payers, ranging from \$9 to \$13 billion *in addition* to the costs associated with diabetes itself (Rice et al, 2014).

**Negative pressure wound therapy (NPWT):** A sealed, air-tight vacuum wound-care system using foam dressings with the application of negative pressure in order to drain exudates and promote blood flow to the wound to enhance healing.

**Peripheral arterial disease:** Systemic form of atherosclerosis causing restrictive blood flow.

**Periwound:** Tissue immediately surrounding the wound.

**Polyneuropathy:** Functional disturbance or pathological changes to the nervous system that may include several systems (motor, sensory, autonomic) typically affecting the lower limbs.

**Pressure injury (also known as pressure ulcer/formerly decubitus ulcer):** Redefined in 2016 as localized damage to skin and underlying soft tissue usually over a bony prominence or related to a medical or other device. The injury occurs as a result of intense and/or prolonged pressure or pressure in combination with shear (NPUAP, 2016).

**SCALE (Skin Changes At Life's End) ulcers:** Term used to describe wounds that appear in terminal clients shortly before death. These ulcers usually develop on the sacrum or coccyx, develop rapidly (sometimes in hours), and are characteristically pear, butterfly, or horseshoe shaped. The shunting of blood (away from the skin and toward the vital organs) results in the skin not receiving inadequate nutrient and oxygen, leading to waste tissue death. *Note:* The Kennedy Terminal Ulcer is a subset of SCALE (WOUNDS Staff, 2009). Treatment is focused on comfort rather than healing.

**Shear:** Normal mechanical force with physiological effects, although it is unclear how it causes tissue damage and is difficult to measure. Change in position or posture is likely to cause shear both externally (friction) and internally.

**Slough:** Necrotic tissue that is separating from the wound bed or surrounding tissue. This tissue can be yellow, tan, gray, brown, or green.

**Venous stasis:** Impaired venous blood flow.

## RELATED CONCERNS

\*\*\*\*In addition to any care plan concerning chronic conditions, surgery, trauma, immobility:

Surgical intervention, page 873

Total nutritional support: parenteral/enteral feeding, page 525

## CLIENT ASSESSMENT DATABASE

Data depend on type, severity, and body surface area involved.

### DIAGNOSTIC DIVISION MAY REPORT

### MAY EXHIBIT

#### ACTIVITY/REST

- Bedrest/wheelchair-bound, immobile, or with limited ability to reposition self
- Decreased strength and/or range of motion (affected extremity)

- Requires assistance for turning, repositioning, weight shifts

#### CIRCULATION

- Diminished or absent dorsalis pedis or posterior tibial pulse (if foot ulcer present)
- Dependent rubor, pallor on elevation, and loss of hair on the foot or toes (may be present in leg and foot ulcers)
- Capillary refill greater than 3 seconds
- Edema of lower extremities

#### ELIMINATION

- Diarrhea, urinary incontinence (may be impacting sacral area skin)

#### NEUROSENSORY

- Paresthesias

#### PAIN/DISCOMFORT

- Pain from the condition causing the wound may or may not be present or be persistent, even at rest, and chronic. Pain present during dressing changes may be acute and associated with activities of debridement.

- Grimacing, withdrawal
- Guarding of affected area
- Emotional responses

#### SAFETY

- Elevated temperature; fever
- Skin ulcerations, wounds
- Foul-smelling drainage, spontaneously bleeding wound bed; increased levels of wound exudate; surrounding cellulitis

#### TEACHING/LEARNING

- History of smoking

#### DISCHARGE PLAN CONSIDERATIONS

- May require assistance with treatments, wound care and supplies, self-care activities, homemaker and maintenance tasks, transportation, finances, and vocational counseling

### DIAGNOSTIC STUDIES

#### TEST

#### WHY IT IS DONE

#### WHAT IT TELLS ME

#### BLOOD TESTS

- **Complete blood count (CBC):** Evaluates numbers and characteristics of blood cells, including red and white blood cells, hemoglobin, hematocrit, and platelets.

Leukocytosis, anemia, and thrombocytopenia are commonly found.

WHY IT IS DONE (continued)	WHAT IT TELLS ME (continued)
<ul style="list-style-type: none"> <li><b>Serum protein, albumin, prealbumin, and transferrin levels:</b> Measures types and efficiency of plasma proteins. Used to detect protein-calorie malnutrition.</li> <li><b>Wound cultures:</b> Specimens obtained from wound bed exudates are cultured to detect a wound infection and to determine which specific bacteria are present.</li> </ul>	<p>May be done to evaluate the client's nutritional status in the setting of nonhealing wounds.</p> <p>May be done to determine the appropriate antimicrobial therapy.</p>
<p><b>ASSOCIATED DIAGNOSTIC STUDIES</b></p> <ul style="list-style-type: none"> <li><b>Vascular studies (e.g., plethysmography, pulse-volume recordings [PVRs]), Doppler Ankle Brachial Pressure Index (ABPI)</b></li> <li><b>Vascular ultrasonography:</b> Noninvasive procedure that uses ultrasound technology to provide information about the anatomy, physiology, and pathology of both the superficial and the deep venous systems.</li> <li><b>Wound biopsy:</b> Piece of viable wound tissue obtained with scalpel or punch biopsy instrument and submitted for microscopic examination.</li> </ul>	<p>May be done to evaluate hemodynamic significance of arterial occlusive disease. <i>Note:</i> Doppler ABPI may be indicated if pulse is not palpable or to assess the appropriateness of high or modified compression bandaging for venous ulcers.</p> <p>May be indicated to evaluate for vessel disease or deep venous occlusion.</p> <p>Recommended in the case of refractory, nonhealing ulcers or when wounds present with atypical signs. <i>Note:</i> A recent study showed that approximately 10% of wounds are atypical (not originating from vascular insufficiency, neuropathy, or prolonged pressure) and are the result of infection, metabolic disorders, neoplasms, and inflammatory processes (Tang et al, 2012).</p>

## NURSING PRIORITIES

- Promote healing.
- Alleviate pain.
- Prevent complications.
- Provide information about wound, treatment, and potential complications.

## DISCHARGE GOALS

- Wound healing progressing toward resolution.
- Pain controlled or reduced.
- Complications prevented or minimized.
- Plan in place to meet discharge needs.

## NURSING DIAGNOSIS: Impaired Skin/Tissue Integrity

### May Be Related To

Mechanical factors (e.g., shearing forces, pressure, restraint)  
 Imbalanced nutritional state (e.g., obesity, emaciation); pressure over bony prominence  
 Excessive/insufficient fluid volume [presence of edema]  
 Moisture, excretions, secretions  
 Impaired circulation (e.g., medical conditions affecting circulation and immune functioning such as diabetes, peripheral neuropathy, peripheral arterial disease and venous insufficiency); alteration in sensation; peripheral neuropathy  
 Extremes of age; impaired mobility

### Possibly Evidenced By

Alteration in skin integrity, damaged/destroyed tissue (e.g., skin layers, subcutaneous tissues)

### Desired Outcomes/Evaluation Criteria—Client Will

#### Wound Healing: Secondary Intention NOC

Be free of signs of infection or other complications.  
 Display progressive improvement/healing of lesions, wounds, or pressure sores.

#### Self-Management: Chronic Disease NOC

Maintain optimal physical well-being.  
 Participate in prevention measures and treatment program.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Wound Care: Nonhealing NIC</b> <i>Independent</i> Review client factors that may delay or inhibit healing.	Client's ability to heal is affected by underlying conditions (e.g., diabetes, poor systemic circulation, or peripheral vascular disease [PVD], malnutrition/protein deficiency); persistent inflammation; use of certain medications (e.g., systemic steroids, immunosuppressive drugs, antimetabolite chemotherapy). Note: Chronic wounds (those with stalled healing or failure to heal) are more prevalent in older adults and are attributed to aged skin and comorbidities, such as neuropathy, arterial compromise, edema, and unrelieved pressure (in addition to factors listed above).
Determine client's age and developmental level. Note presence of compromised mobility, sensation, vision, hearing, or speech.	Factors that affect client's ability to provide for own safety needs (e.g., diabetic with impaired vision cannot satisfactorily examine own feet) or participate in care of skin/tissue wounds.
Assess nutritional status and potential for delayed healing.	Protein-calorie malnutrition and deficiencies of vitamins A, C, and zinc impair normal wound-healing mechanisms (Daley & Bhat, 2017).
Review medication regimen.	Identifies medications that may impair healing (e.g., corticosteroids).
Perform routine skin inspection(s), describing observed changes. Note skin color, turgor.	Provides information about client's general nutrition and hydration status.
Ascertain if wound is acute (e.g., injury from surgery, trauma, new pressure area) or chronic (e.g., venous or arterial insufficiency, longstanding diabetic foot ulcer).	Clarifies intervention needs and priorities.
Assess, monitor, and document wound history and physical examination (using facility protocols and tools and/or using a mnemonic [MEASURE]) (see below) if helpful:	Facilitates determination of healing and if appropriate dressing modality is being used. Note: Documentation of a detailed assessment such as MEASURE or TIME ( <u>tissue</u> , <u>i</u> nflammation or infection, <u>m</u> oisture, <u>e</u> dges of wound) is a legal requirement from both an organizational and professional standards perspective (Ayello et al, 2011; Keast et al, 2004).
M = measure (once/week or per protocol)	Accurate measurement of the wound provides data of wound progress. Note: Keast et al suggest measuring size—longest length with the widest width—at right angles. Recent measuring innovations include tracing grid, digital planimetry, handheld scanner (works by measuring changes in moisture under the skin) (Stephenson, 2015).
E = exudate	Describes amount (none, scant, moderate, or heavy) and characteristics—serous, sanguineous, pustular, or combinations.
A = appearance	Describes appearance of wound bed, slough, and tissue: for example, base: necrotic (black), fibrin (firm yellow), slough (soft yellow), or granulation tissue (pink and healthy vs red and friable = easy bleeding, unhealthy).
S = suffering	Describes pain client is experiencing from underlying condition as well as that which is occurring due to dressing changes and debridement.
U = undermining	It is suggested to measure in centimeters and use hands of clock (e.g., 2 o'clock, 6 o'clock) to document direction of undermining.
E = edge	Describes perimeter tissue (e.g., macerated, normal).
Note odors emitted from skin, wound, or dressings.	May provide information about presence of inflammation in deep tissues or wound infection.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
When performing dressing changes and cleansing wound beds:	
Gently remove tape or old dressing in the direction of hair growth.	Decreases pain during removal of dressing and prevents damage to periwound skin.
Cleanse wound as needed with normal saline or prescribed solution and gently pat dry with gauze sponge.	Removal of necrotic debris facilitates removal of exudate, contaminated or infected tissue and promotes healing.
Apply wound dressing product according to manufacturer's directions.	Using the product correctly will facilitate wound healing and limit/prevent disruption of the periwound skin.
Loosely fill wound cavity with designated product (gauze sponge, alginate), if appropriate for the wound environment.	Tightly packing the wound cavity results in slow wound healing.
<b>Collaborative</b>	
Review laboratory results, for example, hemoglobin (Hgb)/hematocrit (Hct), blood glucose, albumin/proteins, and so on.	These studies may reveal concerns related to underlying conditions (e.g., anemia, systemic hypoxia, diabetes, malnutrition) affecting healing.
Select wound dressing that is appropriate to the wound environment:	There is no one-size fits-all treatment for wound care. Treatments are entirely dependent on underlying condition(s), type, reason for wound healing failure, and characteristics of wound. Some potential treatments are as follows (Daley & Bhat, 2017; Wound Care Center Staff, n.d.):
Wet-to-dry	This coverage requires wet-to-damp dressings, which support autolytic <b>debridement</b> , absorb exudate, and protect surrounding normal skin. Note: In many settings, wet-to-dry dressings are being discarded in favor of more recent forms of debridement (Dale & Wright, 2011).
Hydrocolloid (e.g., DuoDerm, IntraSite)	Useful in providing hydration to dry wound bed and are impermeable to moisture and bacteria and oxygen.
Polyvinyl film (e.g., Op-Site, Tegaderm)	Wounds that are neither dry nor highly exudative may be covered with a polyvinyl film dressing.
Absorptive dressings (e.g., alginate [Kaltostat, Curasorb], impregnated gauze dressings [Mesalt]); hydrofiber (AquaCel, AquaCel-AG)	Wounds (especially deep wounds) with excessive drainage require absorptive dressings.
Foam and other compression dressings (e.g., Biatain, Tegaderm roll, Profore)	Various compression systems are available utilizing with multiple layers, each providing specific benefits for aiding in the wound-healing process. The first layer goes directly on the wound, with subsequent layers providing padding, dressing, and light compression (Wound Care Center Staff, n.d.).
Negative pressure wound therapy (NPWT), also called vacuum-assisted therapy.	A sealed wound-care system that has been found to be useful in the treatment of diabetic ulcers, large chronic wounds, and acute complicated wounds. NPWT removes edema fluid from the wound through suction, resulting in increased blood flow to the wound and greater cell proliferation. A benefit of fluid removal is reduction in bacterial colonization of the wound, reducing the risk of wound infection, and enhancing the formation of granulation tissue (Wound Care Center Staff, n.d.).

### NURSING DIAGNOSIS: acute/chronic Pain

#### May Be Related To

Physical injury agent—tissue destruction  
Chemical injury agents—excretions, secretions

(continues on page 768)

**NURSING DIAGNOSIS:** **acute/chronic Pain** (continued)**Possibly Evidenced By**

Self-report of intensity and characteristics of pain using standardized scale/instrument  
Guarding behavior; positioning to ease pain  
Expressive behavior—restlessness  
Changes in vital signs (acute)

**Outcomes/Evaluation Criteria—Client Will****Pain Level NOC**

Verbalize relief and/or control of pain or discomfort.  
Appear relaxed; able to sleep/rest appropriately.

**Pain Control NOC**

Engage in use of nonpharmacological relief techniques such as relaxation skills and diversional activities.

**ACTIONS/INTERVENTIONS****RATIONALE****Pain Management: Acute/Chronic NIC****Independent**

Assess pain, noting location, characteristics, and intensity (using an age-appropriate numerical [or similar] coded scale).

Helps evaluate degree of discomfort and effectiveness of analgesia or may reveal developing complications.

Determine the impact of the pain experience on quality of life.

Pain can be debilitating, causing inactivity, loss of work and/or enjoyment of life, weight loss or gain, sleep difficulties, depression, and changes in role and social functioning.

Ensure client receives attentive and adequate analgesic care. Anticipate pain with dressing changes or debridement and medicate accordingly.

Helps to relieve the discomfort. Note: Recent research has focused on pain that a client with chronic wound experiences at other times than with dressing changes. Several studies have indicated that more than 80% of people with a chronic wound reported pain at all times, with half of them rating the pain at moderate to worst pain possible (Nemeth et al, 2004).

Provide anticipatory guidance.

Client should be informed about interventions (e.g., debridement) that can increase pain and participate in decisions about type and timing of analgesia.

Instruct in/encourage use of nonpharmacologic techniques such as relaxation, guided imagery, and visualization. Provide diversional activities.

Helps client refocus attention and promotes coping during debridement or dressing changes, reducing pain and discomfort.

**Collaborative**

Administer medication, such as opioids and nonopioid analgesics, NSAIDs; antidepressants (e.g., amitriptyline [Elavil]) and anticonvulsants (e.g., carbamazepine [Tegretol]); local anesthetics (e.g., foam dressing with local release of ibuprofen); and so on. Utilize patient-controlled analgesia (PCA), as indicated.

Relieves pain, enhances comfort, and promotes rest. Note: Numerous agents have been found to relieve the various components of chronic pain. For example, nociceptive (deep tissue) pain may respond best to opioids and NSAIDs, while neuropathic pain (due to nerve damage) may respond better to antidepressants and anticonvulsants (Woo et al, 2008).

Apply topical analgesic, as appropriate.

May be used to decrease pain with the removal of some dressings, such as the foam used in negative wound pressure therapy.

Implement complementary therapies where indicated, such as nerve stimulation and acupuncture.

May be useful in long-term management of neuropathic pain and encourage growth of healthy tissue.

Assist client/family in developing positive coping strategies. Encourage use of/refer to personal and community resources (e.g., assistive equipment, financial resources, home-health providers, and respite services).

Utilization of available resources to facilitate staying active even when modified activities are required, living a healthy lifestyle, encouraging client/SO to exercise own control in situation, and developing short- and long-term plans for long-term care can promote general well-being and enhance quality of life.

**NURSING DIAGNOSIS:** risk for Infection**Risk Factors May Include**

Alteration in skin integrity—broken skin, traumatized tissue  
Decrease in hemoglobin; leukopenia; suppressed inflammatory response  
Chronic illness—diabetes mellitus, obesity; malnutrition

**Desired Outcomes/Evaluation Criteria—Client Will****Infection Severity NOC**

Achieve wound healing; be free of purulent exudate or other signs of wound infection.  
Verbalize understanding of individual causative or risk factors and ways to prevent complications.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Infection Protection NIC</b>	
<i>Independent</i>	
Inspect condition of any surgical incision or other wound. Note risk factors for occurrence of infection.	Any wound is at risk for infection, but certain conditions can increase that risk, such as complicated surgical or contaminated traumatic wound, comorbidities (e.g., diabetes, vascular insufficiency, obesity), vulnerable age, immunosuppression, and malnutrition, placing the client at high risk for delayed healing or nonhealing of wounds.
Adhere to facility infection control policy regarding hand hygiene and prevention of cross-contamination.	Standardized practice to prevent infection.
Maintain aseptic or clean technique as is appropriate during dressing changes. Dispose of biologic waste as required.	Promotes wound healing and reduces risk of healthcare-associated infections.
Monitor for systemic and localized signs and symptoms of infection.	Early detection of infection allows for timely treatment and prevention of further complications.
<i>Collaborative</i>	
Monitor lab studies, such as absolute granulocyte count (AGC), WBC, and differential count.	Measures the number and vitality of infection-fighting white blood cells.
Collaborate in treatment of underlying condition(s), systemic or local infections, and wound treatment plan.	Underlying condition(s) such as diabetes, peripheral vascular disease, and heart failure will be ongoing. Improvement in those conditions can (or may) improve wound healing. Having those conditions (while potentially implicated in the development of wounds) does not necessarily cause wound infections. However, systemic infections, as well as local wound infections, require treatment (e.g., surgical debridement of infected wound, systemic antibiotics for sepsis) (Daley & Bhat, 2017).

**NURSING DIAGNOSIS:** imbalanced Nutrition: less than body requirements**May Be Related To**

Insufficient dietary intake [biological factors (e.g., disease condition; increased metabolic demands for healing)]

**Possibly Evidenced By**

Food intake less than recommended daily allowance; food aversion

Weight loss with adequate food intake

Insufficient muscle tone

[Abnormal laboratory studies (e.g., decreased albumin, total proteins; electrolyte imbalances)]

**Desired Outcomes/Evaluation Criteria—Client Will****Nutritional Status: Energy NOC**

Demonstrate progress in tissue healing; free of infection.  
Display improved muscle tone and general endurance.

**Nutritional Status: Biochemical Measures NOC**

Display normalization of laboratory values.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Nutrition Therapy NIC</b>	
<b>Independent</b>	
Note age, body build, general strength, activity, and current health conditions (e.g., long-term immobilization, chronic diseases) and treatments.	Helps determine nutritional needs.
Weigh client and observe for emaciation, multiple bony prominences, absence of subcutaneous fat and muscle wasting, loss of hair, fissuring of nails, gum bleeding with brushing, and so on.	May indicate protein-energy malnutrition, especially in the setting of nonhealing wounds.
Evaluate total daily food and fluid intake.	May reveal possible cause of malnutrition and changes that could be made to assist client in receiving needed nourishment for wound healing.
Encourage foods high in protein. Offer protein-rich snacks, fluids between meals throughout the day, especially if client eats small amounts at each meal.	The client will require protein intake of 1.2 to 1.5 g/kg/d (adjusted for individual) for adequate wound healing to occur (Daley & Bhat, 2017; Posthauer, 2016). Adequate fluid intake is required to prevent dehydration due to increased protein intake.
Offer high-calorie supplemental nutrition drinks, preferred food/beverage at appropriate texture. Liberalize restrictive diets as possible.	May be helpful in helping client overcome anorexia and food aversion in order to improve client's potential for wound healing.
<b>Collaborative</b>	
Assist in nutritional status assessment (e.g., Mini Nutritional Assessment [MNA], the Malnutrition Universal Screening Tool [MUST] or similar tools), as indicated.	May be used to evaluate client's current status and predict nutritional needs.
Review laboratory studies (e.g., serum albumin/prealbumin, transferrin, amino acid profile, total lymphocyte count, iron stores, nitrogen balance studies, glucose, liver function tests, electrolytes).	Evaluates client's current nutritional status and response to nutritional interventions. Note: Serum prealbumin is sensitive for relatively acute malnutrition because its half-life is 2 to 3 days (vs 21 d for albumin). A serum prealbumin level of less than 10 g/dL suggests severe protein-calorie malnutrition.
Collaborate in treatment of underlying conditions and factors.	Improving client's nutritional status is often multifaceted, especially if client is debilitated over long period of time. Treating infection, anemia, systemic hypotension, and hypoxemia; correcting poor glucose control in diabetic or nausea associated with cancer therapies; or discontinuing medications that decrease appetite may help client regain ability to heal.
Consult registered dietitian or nutritionist, as indicated.	Aids in constructing dietary prescription with optimal amounts of protein, carbohydrates, fats, and calories within client's eating style, needs, and abilities that facilitates wound healing.
Administer vitamin and/or mineral supplements, liquid protein supplements, enteral or parenteral feedings, as needed.	Replacements needed depend on evidence of a deficiency that is impeding wound healing.

## NURSING DIAGNOSIS: risk for ineffective Health Management

### Possibly Evidenced By

Difficulty with prescribed regimen; failure to include treatment regimen in daily living  
Insufficient knowledge of therapeutic regimen; inadequate cues to action  
Perceived seriousness of condition; excessive demands

### Desired Outcomes/Evaluation Criteria—Client Will

#### Knowledge: Treatment Regimen NOC

Verbalize understanding of condition and treatment needs.  
Demonstrate behaviors to maintain therapeutic regimen.  
Identify and use available resources.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Wound Care: Nonhealing NIC</b> <i>Independent</i>	
Assess complexity of client's care needs, noting whether more than one condition is present at the same time.	These factors affect view of self-care. Client may be overwhelmed, in denial, depressed, or have complications exacerbating care needs.
Ascertain client's knowledge and understanding of condition and treatment needs.	Provides baseline for planning care so that learning may begin where client is in relation to condition and current therapeutic regimen.
Identify individual perceptions and expectations of treatment plan.	May reveal misinformation, unrealistic expectations, or other factors that may interfere with client's willingness or ability to follow therapeutic regimen.
Review wound care procedures (e.g., expected tasks and how to perform them); evaluate degree of difficulty for client:	May reveal factors that could interfere with success of self-care.
Maintaining clean technique during dressing changes	Promotes wound healing and reduces risk of infections.
Monitoring for localized signs of infection	Early detection of infection allows for prompt treatment and prevention of further complications.
Signs and symptoms to report to healthcare provider	Provides mechanism for early intervention if complications are occurring or to identify if client is being overwhelmed by complexity of treatment needs.
Refraining from smoking (refer for support, counseling as desired)	Smoking has been shown to decrease cutaneous blood flow by as much as 40%, which produces ischemia and impairs healing (Rayner, 2006).
Eating nutritious foods, staying well hydrated, and taking prescribed medications	All of these measures are needed to promote wound healing and general health.
Accept client's/SOs evaluation of client's strengths and limitations, and ability to cope and/or adapt to situation.	Client may minimize own strengths or have lack of confidence in abilities, which could be reversed with assistance and positive feedback from others.
Note availability and use of resources for assistance. Provide written information and contact numbers and encourage client/SO to seek out resources.	Client/SO may not have, be aware of, or know how to access available resources.
Mobilize support systems, including family/SO, and make appropriate referrals (e.g., wound-care specialists, social services, home-care services, medical supplies, financial assistance, and counseling).	Success of self-care may depend on support systems to reduce stress in dealing with complex and long-term needs.

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

- **ineffective Coping**—situational crises, vulnerability
- **risk for Infection**—broken skin, traumatized tissue; malnutrition; chronic disease
- **risk for disturbed Body Image**—surgery/trauma; treatment regimen

# Systemic Infections and Immunological Disorders

## SEPSIS/SEPTIC SHOCK

**I. Definition**—Sepsis is defined as life-threatening organ dysfunction caused by a dysregulated host response to infection (Singer et al, 2016). *Note:* Over the past two decades, sepsis has been redefined for clinical care several times (1991, 2001, 2016). This definition reflects the most recent work published by the Third International Consensus Definitions for Sepsis and Septic Shock.

The current definition of *sepsis* replaces the term *severe sepsis* under previous definitions, as it encompasses clinical findings of severe sepsis (Sekel, 2017).

Systemic inflammatory response syndrome (SIRS) criteria were also removed from the sepsis definition in recognition of its lack of specificity (Singer et al, 2016). (See Glossary below.)

### II. Pathophysiology (Angus et al, 2016; Sekel, 2017)

- a. Sepsis is the presence of a systemic inflammatory response to documented or presumed infection, which may progress along a continuum.
- b. Septic shock is a subset of sepsis in which profound circulatory, cellular, and metabolic abnormalities are associated with a greater risk of mortality than with sepsis alone. It produces an inability to maintain adequate tissue perfusion and oxygenation, ultimately causing cellular, and then organ system, dysfunction.
- c. Septic shock is accompanied by profound hypotension persisting despite adequate fluid resuscitation and requiring use of vasopressors to maintain mean arterial pressure (MAP ≥65 mm Hg).

### III. Etiology (Centers for Disease Control and Prevention [CDC], n.d.; Kalil & Bailey, 2017)

- a. Multiple microorganisms associated with sepsis
  - i. Bacteria, fungi, viruses, or rickettsiae
  - ii. Common pathogens: *Streptococcus pneumoniae* or *Staphylococcus aureus*, *Candida*, *Salmonella*, *Escherichia coli*, *Legionella*, *Klebsiella*, *Pseudomonas*
- b. Common origin of infections
  - i. Lungs: pneumonia and other pulmonary infections
  - ii. Abdomen: appendicitis, bowel problems (perforated diverticuli), infection of the abdominal cavity, and gallbladder or liver infections
  - iii. Skin: wounds or cellulitis; punctures, such as from intravenous (IV) lines, intravascular devices, or catheters inserted into the body to administer or drain fluids

- iv. Pelvic and genitourinary: urinary tract: kidneys or bladder (glomerulonephritis, pyelonephritis, cystitis), prostatic obstruction; reproductive organs
- v. Bone and soft tissue infections
- vi. Cardiac infection: more common in clients with history of injection drug use
- c. At-risk populations and risk conditions: Anyone can get an infection, and almost any infection can lead to sepsis. However, certain people are at increased risk for developing sepsis: (1) adults older than 65; (2) people with chronic medical conditions (e.g., diabetes, lung disease, cancer, human immunodeficiency virus [HIV] infection; chronic liver and end-stage kidney disease); (3) those with recent trauma, burns, or major surgeries; (4) people with immunosuppression and immunosuppressive therapies, as well as organ and bone marrow transplants; (5) those with indwelling invasive devices (e.g., central venous catheters, arterial catheters, prosthetic devices, urinary and dialysis catheters, feeding tubes); (6) local infection sites (e.g., abscesses, urinary tract infections, or foreign bodies); and (7) children younger than 1 (*not the focus of this care plan*) (CDC, 2017f; Kilburn et al, 2013).
- d. Risk-prone environments: In **healthcare settings**, sepsis is not restricted to hospitals but also can occur in outpatient and extended-care facilities. In the **community**, sepsis can occur because of unsanitary and/or crowded living conditions, pollution, poor nutrition, immunosuppression, chronic health conditions, improper use of antibiotics, and antibiotic resistance.

### IV. Statistics

- a. Morbidity: A recent Centers for Disease Control and Prevention (CDC) study (2016a) showed that more than 1.5 million people in the United States get sepsis and that 7 in 10 patients who had sepsis had recently used healthcare services or had chronic conditions that required medical care. Sepsis is the sixth most common reason for hospital admission in the United States, and patients with sepsis are more likely to have longer hospital stays with higher costs—along with higher rates of discharge to long-term care—than any other discharge diagnosis (Novosad et al, 2016).
- b. Mortality: The CDC (2016) says that about 250,000 Americans die annually of sepsis and further asserts that

one in three who die in a hospital had sepsis. A study published in the *Morbidity and Mortality Weekly Report (MMWR)* examined varying estimates of sepsis mortality and found that between 1999 and 2014, the annual number of all reported sepsis-related deaths increased 31%, between 1999 and 2014 (CDC, 2016a).

- c. Cost: A study published in 2016 by the Healthcare Cost and Utilization Project (HCUP) rated septicemia as number 1 among the 20 costliest conditions treated in U.S. hospitals in 2013 at almost \$24 billion, accounting for 6.2% of aggregate hospital costs. In the same year, Medicare was billed more than \$14.5 billion of that \$24 billion total.

## G L O S S A R Y

- Anaerobic infection:** An infection caused by bacteria, called anaerobes, which cannot grow in the presence of oxygen.
- Bacteremia:** The presence of live bacteria in the blood-stream. Bacteremia is similar in some respects to viremia (the presence of a virus in the blood), parasitemia (the presence of a parasite in the blood), or fungemia (presence of a fungus in the blood).
- Body substance isolation (BSI):** Practice of isolating all body substances—blood, urine, feces, sputum, tears, and so on.
- Cytokines:** Protein chemical messengers involved in the inflammatory process, usually from white blood cells (WBCs).
- Disseminated intravascular coagulation (DIC):** Hyper-stimulation of coagulation pathways results in diffuse activation and consumption of coagulation factors, leading to generalized bleeding.
- Endotoxins:** Potentially toxic, natural compounds found inside pathogens such as bacteria.
- Infection:** Inflammatory response to invasion of host tissue by microorganisms.
- Multiple organ dysfunction syndrome (MODS):** Organ dysfunction leading to organ failure with inability to maintain homeostasis.
- The qSOFA score (also known as quickSOFA):** Bedside prompt (i.e., S = sepsis related; O = organ; F = failure; A = assessment) that may identify infected individuals outside the intensive care unit with suspected infection who are at greater risk for a poor outcome. It uses three

criteria, assigning one point each for (1) low blood pressure (systolic blood pressure [SBP]  $\leq$  100 mm Hg), (2) high respiratory rate ( $\geq$  22 breaths per minute), or (3) altered mentation (Glasgow coma scale  $<$  15). The presence of two or more criteria is associated with a poor outcome (qSOFA.org, n.d.).

**Systemic inflammatory response syndrome (SIRS):**

While some patients with infections may fit the SIRS criteria, SIRS may also occur in multiple noninfectious disease states such as trauma, burns, surgery, or pancreatitis (Kaukonen et al, 2015). Although the SIRS criteria have been removed from the current sepsis definition (Singer et al, 2016), they remain useful for the identification of infection and can be used to help broadly identify or screen potential patients at risk for sepsis (Vincent et al, 2016). We are listing them in this edition as some practitioners may still use them in assessing clinical and laboratory findings (i.e., infection with release of endo- or exotoxins activating the inflammatory cascade—local release of cytokines into the circulation in attempt to restore homeostasis; **and** failure of mechanisms leading to a destructive response with loss of circulatory integrity; **and** criteria [two or more]—fever higher than  $100.4^{\circ}\text{F}/38^{\circ}\text{C}$  or lower than  $96^{\circ}\text{F}/36^{\circ}\text{C}$ ; heart rate greater than 90 beats per minute; respiration greater than 20/min or  $\text{PaCO}_2$  less than 32 mm Torr; WBC count greater than  $12,000/\mu\text{L}$ , less than  $4000/\mu\text{L}$ , or greater than 10% of bands or immature cells [Doenges et al, 2014]).

## CARE SETTING

\*\*\*\*Although severely ill individuals will likely receive care in the intensive care unit (ICU), this plan primarily addresses care on an inpatient acute medical-surgical unit. Nursing care in this setting may be assessment and monitoring of the at-risk client with an existing infection.

## CLIENT ASSESSMENT DATABASE

Data depend on the type, location, and duration of the infective process and organ involvement.

### DIAGNOSTIC DIVISION MAY REPORT

### MAY EXHIBIT

#### ACTIVITY/REST

- Fatigue
- Malaise

- Mental status changes—confusion; delirium
- Respiration and heart rate increased with activity or at rest

#### CIRCULATION

- Blood pressure (BP) may be normal, slightly low to normal range—as long as cardiac output remains elevated
- Profound hypotension (late-stage sign)
- Peripheral pulses bounding, rapid (hyperdynamic phase), weak, thready, or easily obliterated
- Heart rate elevated (greater than 90); extreme tachycardia may be present, unless blunted by beta blockers or other medications (in septic shock)
- Heart sounds may include development of  $S_3$
- Dysrhythmias suggest myocardial dysfunction and effects of acidosis and electrolyte imbalance
- Skin warm, dry, flushed (vasodilation) or pale, cold, clammy, mottled (vasoconstriction)

#### ELIMINATION

- Urinary frequency, urgency (current or recent urinary tract infection)
- Diarrhea

- Oliguria, anuria

#### FOOD/FLUID

- Loss of appetite, nausea, vomiting

- Weight loss
- Diminished or absent bowel sounds
- Extremity and generalized edema

#### NEUROSENSORY

- Headache
- Dizziness, fainting

- Restlessness, apprehension, confusion
- Disorientation, delirium, or coma

#### PAIN/DISCOMFORT

- Abdominal tenderness, localized pain or discomfort
- Headache, sinus pain
- Pelvic or flank pain
- Localized limb pain or tenderness

- Tachypnea (respiratory alkalosis) with decreased respiratory depth
- Dyspnea, rapid labored respirations
- Cough—may be productive if pneumonia is source

#### RESPIRATION

- History of recent or current infection, viral illness, cancer therapies, use of corticosteroids, or other immunosuppressant medications
- Presence of invasive lines or catheters

- Temperature usually elevated (greater than 100.4°F [38°C]) but may be normal in elderly or compromised client; may occasionally be lower than normal (less than 96.8°F [36°C])
- Shaking chills
- Poor or delayed wound healing, purulent drainage, or localized erythema
- Petechiae
- Oozing or bleeding from invasive line sites, wounds, and mucous membranes (late sign)

**MAY REPORT (continued)****MAY EXHIBIT (continued)****SEXUALITY**

- Recent childbirth or abortion
- Vaginal or urethral discharge

- Maceration of vulva or purulent vaginal drainage

**TEACHING/LEARNING**

- Chronic, debilitating health problems—liver, renal, cardiac disease; cancer; diabetes mellitus (DM); alcoholism
- History of splenectomy
- Recent surgery or invasive procedures, traumatic wounds
- Antibiotic use—recent or long term

**DISCHARGE PLAN CONSIDERATIONS**

- May require assistance with wound care and supplies, treatments, self-care, and homemaker tasks

♦ Refer to section at end of plan for postdischarge considerations.

**DIAGNOSTIC STUDIES**

TEST	WHY IT IS DONE	WHAT IT TELLS ME
<b>BLOOD TESTS</b>		
• <i>Complete blood count (CBC)</i> :	Battery of screening tests, which typically includes hemoglobin (Hgb); hematocrit (Hct); red blood cell (RBC) count, morphology, indices, and distribution width index; platelet count and size; WBC count and differential, which includes neutrophils, lymphocytes, monocytes, eosinophils, and basophils.	Hct may be elevated in hypovolemic states because of hemoconcentration. Leukopenia, decreased WBCs, occurs early and may be followed by a rebound leukocytosis reflecting rapid production of immature WBCs. Neutrophils may be elevated or depressed. Platelets may be elevated initially as an acute-phase reactant but are decreased in later stages.
• <i>Serum electrolytes</i> :	Substances that will dissociate into ions in solution and acquire the capacity to conduct electricity. Common electrolytes include sodium, potassium, chloride, calcium, and phosphate.	Various imbalances may occur because of acidosis, fluid shifts, and altered renal function.
• <i>Biomarkers, such as acute-phase reactants</i>		Literature review indicates that many biomarkers can be used in sepsis, but none has sufficient specificity or sensitivity to be routinely employed in clinical practice. procalcitonin (PCT) and C-reactive protein (CRP) have been most widely used, but even these have limited abilities to distinguish sepsis from other inflammatory conditions or to predict outcome (Clancy et al, 2012). PCT levels rise with severity of illness but also decrease rapidly in client who is responding favorably to treatment (Kaplan, 2017).
• <i>Procalcitonin (PCT)</i> :	Peptide precursor to calcitonin.	Decreased platelet levels (thrombocytopenia) can occur because of platelet aggregation.
• <i>Clotting studies:</i>	• <i>Platelets</i> : Platelets play an important role in blood coagulation and hemostasis that is often altered by sepsis.	Both PT and aPTT may be prolonged, indicating coagulopathy associated with liver ischemia, circulating toxins, or shock state.
	• <i>Prothrombin time (PT)/activated partial thromboplastin time (aPTT)</i> : Measurement of coagulation times to identify abnormalities common to sepsis and that can lead to life-threatening complications.	
	• <i>Fibrin degradation products</i> : End product of clot breakdown associated with abnormal coagulation process.	Often elevated and associated with tendency to bleed.

(continues on page 776)

## DIAGNOSTIC STUDIES (contd.)

WHY IT IS DONE (continued)	WHAT IT TELLS ME (continued)
<ul style="list-style-type: none"><li><b>Serum lactate:</b> Product of anaerobic cellular metabolism, thus reflecting inflammatory burden and tissue hypoperfusion.</li><li><b>Serum glucose:</b> Glucose is a primary energy source and necessary for cellular function.</li><li><b>Blood urea nitrogen (BUN)/creatinine (Cr):</b> Measurement of organ involvement and indicator of early stage of endotoxin shock.</li><li><b>Arterial blood gases (ABGs):</b> Measures pH level and oxygen and carbon dioxide concentrations in arterial blood.</li></ul>	Elevated levels may correlate with severity of sepsis. Note: Studies show that lactate levels correlate strongly with mortality (Kaplan, 2017). Hyperglycemia occurs in response to insulin resistance and cellular starvation. Hypoglycemia is a predictor of poor prognosis. Increased levels of BUN and Cr are associated with dehydration, renal impairment or failure, and liver dysfunction or failure.
	Early respiratory alkalosis and hypoxemia may occur. In later states, hypoxemia, respiratory acidosis, and lactic and metabolic acidosis occur because of failure of compensatory mechanisms.
	Identifies causative organism(s) and appropriate treatment options. However, clients can deteriorate to full-blown septic shock without an identifiable microbial agent.
	Presence of blood cells, protein, and bacteria in the urine suggests infection.
<b>Imaging studies</b> <ul style="list-style-type: none"><li><b>Chest and abdominal x-rays:</b> Screening procedure to help determine source of infection.</li><li><b>Abdominal ultrasound:</b> Imaging technique that uses high-frequency sound waves to create an image of organs.</li><li><b>Computed tomography (CT) scan or CAT scan:</b> X-ray procedure that uses a computer to produce a detailed picture of a cross section of the body.</li></ul>	Chest x-ray may reveal pneumonia, a common source of infection. Free air in the abdomen may suggest organ perforation caused by infection. Modality of choice when biliary tract source is suspected. Modality of choice when intra-abdominal abscess or other gastrointestinal (GI) tract disorders are suspected.

## NURSING PRIORITIES

1. Eliminate infection.
2. Support tissue perfusion or circulatory volume.
3. Prevent complications.
4. Provide information about disease process, prognosis, and treatment needs.

## DISCHARGE GOALS

1. Infection eliminated or controlled.
2. Homeostasis maintained.
3. Complications prevented or minimized.
4. Disease process, prognosis, and therapeutic regimen understood.
5. Plan in place to meet needs after discharge.

### NURSING DIAGNOSIS: risk for Infection [progression; opportunistic/hospital-acquired]

#### Possibly Evidenced By

Immunosuppression; suppressed inflammatory response (e.g., steroid use); leukopenia  
Stasis of body fluid; alteration in skin integrity  
Invasive procedures; [exposure to multiple healthcare workers and care settings]

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Infection Severity NOC

Be free of signs of infection [or progressive infections] such as fever, purulent secretions, wound drainage, erythema, or failure to heal.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Infection Control NIC</b>	
<b>Independent</b>	
Examine client for possible source of infection, such as sore throat, sinus pain, burning with urination, localized abdominal pain, burns, open wounds or cellulitis, presence of invasive catheters, or lines.	Respiratory tract and urinary tract infections are the most frequent causes of sepsis, followed by abdominal and soft tissue infections. The use of intravascular devices is also a well-known cause of hospital-acquired sepsis.
Ensure multidisciplinary involvement in hand hygiene. Wash hands with antibacterial soap before and after each care activity, even when gloves are used.	Hand washing and hand hygiene reduce the risk of cross-contamination. Note: Methicillin-resistant <i>Staphylococcus aureus</i> (MRSA) is most commonly transmitted via direct contact with healthcare workers who fail to wash hands between client contacts. Healthcare professionals must assume responsibility for reducing risk of infection spread by observing strict hand hygiene and other infection-reducing measures (Bosek & Shaner-McRae, 2010; Johnson et al, 2011).
Provide isolation and monitor visitors, as indicated.	Body substance isolation (BSI) should be used for all infectious clients. Wound and linen isolation and hand washing may be all that is required for draining wounds. Clients with diseases transmitted through air may also need airborne and droplet precautions. Reverse isolation and restriction of visitors may be needed to protect the immunosuppressed client.
Encourage or provide frequent position changes, deep-breathing and coughing exercises.	Good pulmonary toilet may reduce respiratory compromise.
Encourage client to cover mouth and nose with tissue when coughing or sneezing. Place in private room if indicated. Wear mask when providing direct care as indicated.	Appropriate behaviors, personal protective equipment, and isolation prevent spread of infection via airborne droplets.
Limit use of invasive devices and procedures when possible. Remove lines and devices when infection is present and replace if necessary.	Reduces number of possible entry sites for opportunistic organisms.
Inspect wounds and sites of invasive devices daily, especially parenteral nutrition lines. Document signs of local inflammation and infection and changes in character of wound drainage, sputum, or urine.	Catheter-related bloodstream infections have increased where central venous catheters are used in both acute and chronic care settings. Clinical signs, such as local inflammation or phlebitis, may provide a clue to portal of entry, type of primary infecting organism(s), and early identification of secondary infections.
Investigate reports of pain out of proportion to visible signs.	Pressure-like pain over area of cellulitis may indicate development of necrotizing fasciitis due to group A beta hemolytic streptococci (GABS), necessitating prompt intervention.
Maintain sterile technique when changing dressings, suctioning, and providing site care, such as an invasive line or a urinary catheter.	Medical asepsis prevents or limits introduction of bacteria and reduces the risk of healthcare-associated infection.
Wear gloves and gowns when caring for open wounds or anticipating direct contact with secretions or excretions.	Prevents spread of infection and cross-contamination.
Dispose of soiled dressings and other materials in double bag.	Appropriate disposal of contaminated materials reduces spread of organisms.
Note temperature trends and observe for shaking chills and profuse diaphoresis.	Fever (101°F–105°F [38.5°C–40°C]) is the result of endotoxin effect on the hypothalamus and pyrogen-released endorphins. Hypothermia lower than 96.8°F (36.8°C) is a grave sign reflecting advancing shock state, decreased tissue perfusion, and/or failure of the body's ability to mount a febrile response. Chills often precede temperature spikes in presence of generalized or new-onset infection.

(continues on page 778)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Monitor for signs of deterioration of condition or failure to improve with therapy.	Deterioration of clinical condition or failure to improve with therapy may reflect inappropriate or inadequate antibiotic therapy or overgrowth of resistant or opportunistic organisms.
Inspect oral cavity for white plaques. Investigate reports of vaginal and perineal itching or burning.	Depression of immune system and use of antibiotics increase the risk of secondary infections, particularly yeast—thrush.
<b>Collaborative</b>	
Obtain specimens of urine, blood, sputum, wound, and invasive lines or tubes for culture and sensitivity, as indicated.	Identification of portal of entry and organism causing the infection is crucial to effective treatment based on susceptibility to specific medications.
Monitor laboratory studies, such as WBC count with neutrophils and band counts.	The normal ratio of neutrophils to total WBCs is at least 50%; however, when WBC count is markedly decreased, calculating the absolute neutrophil count is more pertinent to evaluating immune status. Likewise, an initial elevation of band cells reflects the body's attempt to mount a response to the infection, whereas a decline indicates decompensation.
Administer medications, as indicated, for example:	
Anti-infective agents: <b>broad-spectrum antibiotics</b> , such as imipenem and cilastatin (Primaxin), meropenem (Merrem), piperacillin and tazobactam (Zosyn), clindamycin (Cleocin), vancomycin (Vancocin); <b>aminoglycosides</b> , such as tobramycin (Nebcin), gentamicin (Garamycin); <b>cephalosporins</b> , such as cefepime (Maxipime); trimethoprim/sulfamethoxazole (Bactrim DS); aztreonam (Azactam); <b>fluoroquinolones</b> , such as levofloxacin (Levaquin), ciprofloxacin (Cipro); daptomycin (Cubicin), tigecycline (Tygacil) (not a complete listing)	Specific antibiotics are determined by culture and sensitivity tests, but therapy is usually initiated before obtaining results, using broad-spectrum antibiotics and/or based on most likely infecting organisms. Note: The choice of antimicrobials can be complex and should consider the patient's history (e.g., recent antibiotics received, previous infecting organisms); comorbidities (e.g., diabetes, organ failures), immune defects (e.g., HIV); probable location of current acquired infection (e.g., community or healthcare); suspected site of infection (e.g., lungs, gut, wound); and presence of invasive devices (Cunha, 2017; Schmidt & Mandel, 2017).
Antifungals, such as fluconazole (Diflucan), caspofungin (Cancidas)	Antifungal therapy may be considered in client who has already been treated with antibiotics, who is neutropenic, receiving total parenteral nutrition (TPN), or who has central venous access in place (Kaplan, 2017).
Assist with or prepare for procedures, such as removal of infected devices, incision and drainage of abscess, or debridement of infected wounds, as indicated.	Removal of infection sources promotes healing. Note: Certain conditions will not respond to standard treatment for septic shock until the source of infection is surgically removed (e.g., intra-abdominal sepsis [perforation, abscesses], mediastinitis, pancreatic abscesses, septic arthritis, infected prosthetic devices, perirectal abscess, and necrotizing fasciitis) (Kalil & Bailey, 2017).
Prepare for hyperbaric therapy, as appropriate.	Exposing wounds to high ambient oxygen tension therapy may be done to combat anaerobic infections.

## NURSING DIAGNOSIS: Hyperthermia

### May Be Related To

Illness, sepsis—[direct effect of circulating endotoxins on the hypothalamus]  
Increased metabolic rate  
Dehydration

### Possibly Evidenced By

[Increase in body temperature above normal range]  
Flushed skin; skin warm to touch; vasodilation  
Tachypnea, tachycardia

**NURSING DIAGNOSIS:** **Hyperthermia** (continued)**Desired Outcomes/Evaluation Criteria—Client Will****Thermoregulation NOC**

Demonstrate temperature within normal range and be free of chills.  
Experience no associated complications.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Fever Treatment NIC</b>	
<i>Independent</i>	
Monitor client temperature—degree and pattern. Note shaking chills or profuse diaphoresis.	Temperature of 102.8°F to 106.8°F (38.9°C–41.1°C) suggests acute severe infectious disease process. Fever pattern may aid in diagnosis. Chills often precede temperature spikes. Note: Use of antipyretics alters fever patterns and may be restricted until diagnosis is established unless fever remains higher than 102.8°F (38.9°C).
Monitor environmental temperature. Limit or add bed linens, as indicated.	Room temperature and linens should be altered to maintain near-normal body temperature.
Provide tepid sponge baths. Avoid use of alcohol.	Tepid sponge baths may help reduce fever. Note: Use of ice water or alcohol may cause chills, actually elevating temperature. Alcohol can also cause skin dehydration.
<i>Collaborative</i>	
Administer antipyretics, such as acetylsalicylic acid (ASA) (aspirin) or acetaminophen (Tylenol).	Antipyretics reduce fever by its central action on the hypothalamus; fever should be controlled in clients who are neutropenic or asplenic. However, fever may be beneficial in limiting growth of organisms and enhancing auto-destruction of infected cells.
Provide cooling blanket, or hypothermia therapy, as indicated.	Used to reduce fever, especially when higher than 104.8°F to 105.8°F (39.5°C–40°C) and when seizures or brain damage are likely to occur.

**NURSING DIAGNOSIS:** **risk for Shock****Possibly Evidenced By**

Infection; sepsis; systemic inflammatory response syndrome (SIRS)  
Relative or actual hypovolemia; hypotension

**Desired Outcomes/Evaluation Criteria—Client Will****Shock Severity: Sepsis NOC**

**Display adequate perfusion as evidenced by stable vital signs, palpable peripheral pulses, skin warm and dry, usual level of mentation, individually appropriate urinary output, and active bowel sounds.**

ACTIONS/INTERVENTIONS	RATIONALE
<b>Shock Prevention NIC</b>	
<i>Independent</i>	
Monitor trends in blood pressure (BP), especially noting progressive hypotension and widening pulse pressure.	Hypotension develops as circulating microorganisms stimulate release and activation of chemical and hormonal substances. These endotoxins initially cause peripheral vasodilation, decreased systemic vascular resistance (SVR), and relative hypovolemia. As shock progresses, cardiac output becomes severely depressed due to major alterations in contractility, preload, and/or afterload, thus producing profound hypotension.

(continues on page 780)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Monitor heart rate and rhythm. Note dysrhythmias.	Tachycardia occurs because of sympathetic nervous system stimulation secondary to stress response and to compensate for the relative hypovolemia and hypotension. Cardiac dysrhythmias can occur because of hypoxia, acid-base and electrolyte imbalance, and/or low-flow perfusion state.
Note quality and strength of peripheral pulses.	Initially, the pulse is strong and bounding because of increased cardiac output. Pulse may become weak and thready because of sustained hypotension, decreased cardiac output, and peripheral vasoconstriction if the shock state progresses.
Assess respiratory rate, depth, and quality. Note onset of severe dyspnea.	Increased respirations occur in response to direct effects of endotoxins on the respiratory center in the brain, as well as developing hypoxia, stress, and fever. Respirations become shallow as respiratory insufficiency develops, creating risk of acute respiratory failure.
Investigate changes in sensorium—mental cloudiness, agitation, restlessness, personality changes, delirium, stupor, and coma.	Changes in mentation reflect alterations in cerebral perfusion, hypoxemia, and/or acidosis.
Assess skin for changes in color, temperature, and moisture.	Vasodilation results in the warm, dry, pink skin characteristic of hyperperfusion in hyperdynamic phase of early septic shock. If shock state progresses, compensatory vasoconstriction occurs, shunting blood to vital organs, reducing peripheral blood flow, and creating cool, clammy, pale, and dusky skin.
Record hourly urinary output and specific gravity.	Decreasing urinary output with high specific gravity indicates diminished renal perfusion related to fluid shifts and selective vasoconstriction. There may be transient polyuria during hyperdynamic phase, while cardiac output is elevated, but this may progress to oliguria.
Auscultate bowel sounds.	Reduced blood flow to the mesentery (splanchnic vasoconstriction) decreases peristalsis and may lead to paralytic ileus or possibly trigger multiple organ dysfunction syndrome (MODS).
Hematest gastric secretions and stools for occult blood.	Stress of illness and use of steroids increase risk of gastric mucosal erosion and bleeding.
Evaluate lower extremities for local tissue swelling, erythema, and positive Homans' sign.	Venous stasis, changes in the coagulation processes, and infection may result in the development of thrombosis.
Maintain sequential compression devices (SCDs), as indicated.	These are preventive measures for bedfast client to reduce lower-extremity stasis complications.
Monitor for signs of bleeding: oozing from puncture sites or suture lines, petechiae, ecchymoses, hematuria, epistaxis, hemoptysis, and hematemesis.	Coagulopathies such as DIC may occur, related to accelerated clotting in the microcirculation reflecting activation of chemical mediators, vascular insufficiency, and cell destruction, creating a life-threatening hemorrhagic situation and multiple emboli.
Note drug effects, and monitor for signs of toxicity.	Massive doses of antibiotics have potentially toxic effects in clients with compromised renal and/or hepatic function.
<b>Collaborative</b>	
Administer parenteral fluids. (Refer to ND: risk for deficient Fluid Volume, following.)	Parenteral fluid therapy helps maintain tissue perfusion and expand circulating volume.
Administer medications, as indicated, for example:	
Corticosteroids	Although steroid therapy remains controversial, low-dose steroids may be given for the potential advantages of decreasing capillary permeability, increasing renal perfusion, and inhibiting microemboli formation. Note: Studies show that in patients without shock (or with less severe septic shock), glucocorticoid therapy does not appear to be beneficial. Other studies suggest that glucocorticoid therapy is most likely to be beneficial in

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Vasoactive agents, such as norepinephrine (Levophed), dopamine (Intropin), dobutamine (Dobutamine), vasopressin (Pitressin); milrinone (Primacor) (Kalil & Bailey, 2017)	patients who have severe septic shock despite adequate fluid resuscitation and vasopressor administration (Kaufman & Mancebo, 2016).
Low-molecular-weight heparin, such as enoxaparin (Lovenox), dalteparin (Fragmin), and tinzaparin (Innohep), and unfractionated heparin	Inotropic agents and vasopressors may be needed to improve organ perfusion and to maintain blood pressure during and after fluid treatment. Note: Client needing this level of support is critically ill and will be treated in the ICU.
Histamine-2 receptor blockers, such as cimetidine (Tagamet), famotidine (Pepcid AC), nizatidine (Asid), and ranitidine (Zantac).	Low-molecular-weight heparin prevents or treats deep vein thrombosis (DVT). (Refer to CP: Venous Thromboembolism [VTE] Disease including Deep Vein Thrombosis [DVT] and Pulmonary Embolism [PE] for associated assessments and interventions.)
Monitor laboratory studies, such as ABGs and lactate levels.	Histamine receptor blockers prevent or treat stress ulcers.
Provide supplemental oxygen by appropriate route.	Circulatory collapse reduces tissue perfusion. Inadequate renal perfusion alters filtration, reabsorption, and secretion of various substances, resulting in fluid and electrolyte imbalances. ABGs and serum lactate levels indicate acid-base balance and anaerobic metabolism. Respiratory or metabolic acidosis indicates weakened compensatory mechanisms. Lactic acid accumulation is due to inadequate oxygenation and thus accumulation of anaerobic by-products or lactate.
Maintain stable body temperature, using adjunctive aids as necessary. (Refer to ND: Hyperthermia.)	Supplemental oxygen improves cellular oxygenation.
Prepare for and transfer to critical care setting, as indicated.	Temperature elevations increase metabolic and oxygen demands beyond cellular resources, hastening tissue ischemia and cellular destruction.
	Temperature elevations increase metabolic and oxygen demands beyond cellular resources, hastening tissue ischemia and cellular destruction.
	Progressive deterioration requires more aggressive therapy, including hemodynamic monitoring and vasoactive drug infusions.

### NURSING DIAGNOSIS: risk for deficient Fluid Volume

#### Possibly Evidenced By

Active fluid volume loss [e.g., hemorrhage; diarrhea, vomiting, draining wounds]  
Compromised regulatory mechanisms [relative fluid loss, e.g., massive vasodilation, capillary permeability with fluid leaks into the interstitial space (third spacing); sequestration of fluid in peritoneal cavity]  
Insufficient fluid intake [i.e., fluid resuscitation]

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Hydration NOC

Maintain adequate circulatory volume as evidenced by vital signs within client's normal range, palpable peripheral pulses of good quality, and individually appropriate urinary output.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Shock Prevention NIC</b>	
<b>Independent</b>	
Measure and record urinary output and specific gravity. Note cumulative intake and output (I&O) imbalances (including insensible losses), and correlate with daily weight. Encourage oral fluids, as tolerated.	Decreasing urinary output with a high specific gravity suggests relative hypovolemia associated with vasodilation. Continued positive fluid balance with corresponding weight gain may indicate third spacing and tissue edema, suggesting need to alter fluid therapy or replacement components. Note: Excessive diarrhea may lead to a negative fluid balance.

(continues on page 782)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Monitor BP and heart rate. Measure central venous pressure (CVP) if used.	Reduction in the circulating fluid volume reduces BP and CVP, initiating compensatory mechanisms of tachycardia to improve cardiac output and increase systemic blood pressure.
Palpate peripheral pulses.	Weak, easily obliterated pulses suggest hypovolemia.
Assess for dry mucous membranes, poor skin turgor, and thirst.	Hypovolemia and third spacing of fluid give rise to signs of dehydration.
Observe for dependent or peripheral edema in sacrum, scrotum, back, and legs.	Fluid losses from the vascular compartment into the interstitial space create tissue edema.
<b>Collaborative</b>	
Administer IV fluids, such as isotonic crystalloids ( $D_5W$ , normal saline [NS], lactated Ringer's [LR]), and colloids (albumin, fresh-frozen plasma), as indicated.	Fluid therapy is most effective early in the course of severe sepsis. The amount and rate of infusion are guided by assessment of the patient's vital signs, mentation, and cardiovascular status.
Monitor laboratory values, such as the following:	
Hct/RBC count	Evaluates changes in hydration/blood viscosity.
BUN/Cr	The BUN/Cr ratio could indicate dehydration or renal dysfunction and failure.
Monitor cardiac output, as indicated.	Cardiac output and other functional parameters, such as cardiac index, preload, afterload, contractility, and cardiac work, can be measured noninvasively using thoracic electrical bioimpedance (TEB) technique. Cardiac output determination is useful in determining therapeutic needs and effectiveness.

### NURSING DIAGNOSIS: risk for acute Confusion

#### Possibly Evidenced By

Infection; alteration in cognitive functioning; alteration in sleep-wake cycle; sensory deprivation  
Dehydration, malnutrition  
Impaired metabolic functioning (e.g., electrolyte imbalance, azotemia)  
Pharmaceutical agents—multiple medications

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Cognition NOC

Maintain usual level of consciousness and cognition.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Delirium Management NIC</b>	
<b>Independent</b>	
Note presence of factors that can contribute to confusion.	Disease process of sepsis (e.g., presence of circulating toxins, fluid and electrolyte imbalances, and fever) can contribute to confusion.
Assess mental/cognitive status, noting alertness, orientation, attention span, appropriateness of verbal responses.	Helps to identify a potential cognitive decline, possibly manifested by confusion.
Monitor temperature and note trends.	Although fever is usually present, hyperthermia can lead to confusion. It is important to determine if fever is related to the environment or to alterations in client metabolic processes.
Evaluate nutritional status.	Deficiencies of essential nutrients can affect mental status.
Note sleep/rest problems.	Sleep deprivation due to disease process or intensity of treatment interventions and environment can cause confusion.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Monitor intake and output; offer fluids accordingly.	Dehydration and electrolyte imbalances can cause or exacerbate confusion.
Encourage deep breathing or use of incentive spirometer.	Promotes respiratory function, improving oxygenation of brain tissues, which may improve cognitive function.
<b>Collaborative</b>	
Monitor ABGs, pulse oximetry, and end-tidal CO <sub>2</sub> .	Identifies hypoxemia and hypercarbia, which may lead to altered cerebral functioning. Managing acid-base and metabolic imbalances can help minimize alterations in cerebral function.
Assist with treatment of underlying disease process.	As infection subsides, potential for confusion is reduced as well.
Administer fluids and electrolyte replacements as indicated.	Managing fluid, acid-base, and electrolyte imbalances can help minimize alterations in cerebral function.
Administer supplemental oxygen, as indicated.	Increases oxygen saturation and improves cerebral perfusion and function.
Administer nutritional support as indicated.	Increased metabolic rate associated with illness and fever can result in nutritional deficits, especially when client is too ill for oral intake and/or gastrointestinal motility is decreased.

### NURSING DIAGNOSIS: risk for impaired Gas Exchange

#### Possibly Evidenced By

Alveolar-capillary membrane changes—increased capillary permeability leading to pulmonary congestion  
Abnormal breathing pattern—effects of endotoxins on the respiratory center in the medulla resulting in hyperventilation and respiratory alkalosis; hypoventilation  
[Interference with oxygen delivery and utilization in the tissues (endotoxin-induced damage to the cells and capillaries)]

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Respiratory Status: Gas Exchange NOC

Display ABGs and respiratory rate within client's normal range, with breath sounds clear and chest x-ray clear or improving.  
Experience no dyspnea or cyanosis.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Respiratory Monitoring NIC</b>	
<b>Independent</b>	
Maintain client airway. Place client in position of comfort with head of bed elevated 30 to 45 degrees.	Elevating the head of bed enhances lung expansion and reduces respiratory effort.
Monitor respiratory rate and depth. Note use of accessory muscles or work of breathing.	Rapid, shallow respirations occur because of hypoxemia, stress, and circulating endotoxins. Hypoventilation and dyspnea reflect ineffective compensatory mechanisms and are indications that ventilatory support is needed.
Auscultate breath sounds. Note crackles, wheezes, and areas of decreased or absent ventilation.	Respiratory distress and the presence of adventitious sounds are indicators of pulmonary congestion, interstitial edema, and atelectasis. Note: Respiratory complications, including pneumonia and acute respiratory distress syndrome (ARDS), are prime causes of death.
Note presence of circumoral cyanosis.	Circumoral cyanosis indicates inadequate central oxygenation and hypoxemia.
Investigate alterations in sensorium: agitation, confusion, personality changes, delirium, stupor, and coma.	Cerebral function is very sensitive to decreases in oxygenation such as hypoxemia or reduced perfusion.
Note cough and purulent sputum production.	Pneumonia is a common healthcare-acquired infection that can occur by aspiration of oropharyngeal organisms or spread from other sites.

(continues on page 784)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Reposition frequently. Encourage coughing and deep-breathing exercises. Suction, as indicated.	Good pulmonary toilet is necessary for reducing ventilation/perfusion imbalance and for mobilizing and facilitating removal of secretions to maximize gas exchange.
Assess and monitor client for escalating respiratory distress (e.g., respiratory rate >22, shortness of breath, change in skin color). Document and report escalation, and prepare client for transfer to intensive care as indicated.	Most clients with sepsis develop respiratory distress as a manifestation of severe sepsis or septic shock. The lung injury is characterized pathologically as diffuse alveolar damage (DAD) and ranges from acute lung injury (ALI) to moderate or severe acute respiratory distress syndrome (ARDS). These clients need intubation and mechanical ventilation for optimal respiratory support. Intubation should be considered early in the course of progressing severe sepsis. (Refer to CP: Respiratory Failure/Ventilatory Assistance.)
<b>Collaborative</b>	
Collaborate in treatment of underlying condition(s).	Treatment of existing infection (e.g., pneumonia, among others) may prevent escalation to ARDS or other pulmonary complications associated with severe sepsis.
Monitor ABGs and pulse oximetry.	Hypoxemia is related to decreased ventilation and pulmonary changes (e.g., interstitial edema, atelectasis, and pulmonary shunting) and increased oxygen demands caused by fever or infection. Respiratory acidosis (pH below 7.35 and PaCO <sub>2</sub> higher than 40 mm Hg) occurs because of hypoventilation and ventilation-perfusion imbalance. As septic condition worsens, metabolic acidosis (pH below 7.35 and HCO <sub>3</sub> less than 22–24 mEq/L) develops as a result of buildup of lactic acid from anaerobic metabolism.
Review serial chest x-rays.	Changes on x-ray reflect progression or resolution of pulmonary complications, such as infiltrates and edema.
<b>Oxygen Therapy NIC</b>	
Administer supplemental oxygen via appropriate route: nasal cannula, mask, or high-flow rebreathing mask.	Supplemental oxygen is necessary for correction of hypoxemia with failing respiratory effort or progressing acidosis. Note: Intubation and mechanical ventilation and care in ICU may be required if respiratory distress or failure develops.
Administer red blood cells (RBCs), as indicated.	May be required to improve available oxygen to treat sepsis-induced hypoperfusion.

**NURSING DIAGNOSIS:** **deficient Knowledge regarding illness, prognosis, treatment, self-care, and discharge needs**

**May Be Related To**

Insufficient information; insufficient interest in learning; insufficient knowledge of resources  
Misinformation presented by others  
Alteration in cognitive functioning or memory

**Possibly Evidenced By**

Insufficient knowledge  
Inaccurate follow-through of instructions, development of preventable complications

**Desired Outcomes/Evaluation Criteria—Client Will**

**Knowledge: Infection Management NOC**

Verbalize understanding of disease process, prognosis, and potential complications.  
Correctly perform necessary procedures and explain reasons for the actions.  
Initiate necessary lifestyle changes.  
Verbalize understanding of therapeutic needs.  
Participate in treatment regimen.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Teaching: Disease Process NIC</b> <i>Independent</i>	
Review disease process and future expectations with client/SO, as indicated.	Open discussion regarding the disease and clinical expectations provides knowledge base from which client can make informed choices.
Review individual risk factors, mode of transmission, and portal of entry of infections.	Awareness of means of infection transmission provides opportunity to plan for and institute protective measures.
Provide information about drug therapy, interactions, side effects, and importance of adherence to regimen.	Adequate and appropriate information promotes understanding and enhances compliance with treatment or prophylaxis and reduces risk of recurrence and complications.
Discuss need for good nutrition and balanced diet.	Good nutrition is necessary for optimal healing, immune system enhancement, and general well-being.
Encourage adequate rest periods with scheduled activities.	Rest relieves fatigue (which may be present for a long time), conserves energy, and facilitates recovery.
Review necessity of personal hygiene and environmental cleanliness, proper cooking techniques, and food storage.	Personal hygiene and environmental cleanliness reduces exposure to pathogens.
Identify signs and symptoms requiring medical evaluation: persistent temperature elevation(s), tachycardia, syncope, rashes of unknown origin, unexplained fatigue, anorexia, increased thirst, and changes in bladder function.	Early recognition of developing or recurring infection allows for timely intervention and reduces risk for progression to life-threatening situation.
Emphasize importance of prophylactic immunizations and antibiotic therapy, as needed.	Prophylactic vaccines and antibiotics prevent infection, especially in high-risk groups such as those of advanced age or with chronic illness and/or a past history of infective heart disease and immunosuppression.

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

- **risk for [recurrence/opportunistic] Infection**—stasis of body fluids, decreased hemoglobin, leukopenia, suppressed inflammatory response, use of anti-infective agents, increased environmental exposure, malnutrition
- **imbalanced Nutrition: less than body requirements**—biological factors (e.g., increased energy needs [hypermetabolic state], anorexia, continuing GI dysfunction, side effects of medication)
- **Self-Care deficit/Impaired Home Maintenance**—fatigue, pain/discomfort, inadequate support systems, unfamiliarity with neighborhood resources

## THE HIV-POSITIVE CLIENT

### I. Pathophysiology

- a. Infection by a subgroup of retroviruses with a high affinity for CD4 T lymphocytes and monocytes, with viral DNA incorporating itself into host DNA
- b. Following successful transmission of HIV, the course of subsequent infection is variable and dependent on a number of factors.
- c. Main consequence of infection is damage to the immune system.

**II. Stages**—Progression is individually variable, depending on the health of the person's immune system, on CD4 cell count and viral load in the blood, and on the exposure to infections and diseases in the environment (Health24, 2014).

#### a. Primary HIV infection or acute seroconversion stage

- i. Seroconversion usually occurs 4 to 8 weeks after person has been infected with HIV virus.
- ii. Individual may be asymptomatic or develop flu-like symptoms—low-grade fever, sore throat, swollen lymph nodes, rash, joint and muscle pain.
- iii. HIV test is positive, but immune system is usually functional.

- b. **Latency or asymptomatic stage** can last anywhere from weeks to years.
  - i. Virus is active and damaging the immune system, even though client may show no symptoms.
  - ii. Individual may be unaware of HIV status but can still transmit the infection.

(continues on page 786)

- c. **Minor symptomatic phase** usually occurs between 5 and 7 years after infection.
- Immune system is compromised.
  - Client begins to present with one or more symptoms—skin rashes; general feelings of malaise/fatigue; weight loss; mouth ulcers; fungal skin and nail infections, shingles; oral or vaginal thrush; recurrent herpes blisters on mouth or genitals; recurrent upper respiratory infections; occasional fevers.
- d. **Major symptomatic and opportunistic diseases phase (also called AIDS):** Median occurrence is 11 years after being infected.
- Viral load is very high; CD4 count is very low, thus indicating full-blown AIDS.
  - Severe immune system damage and opportunistic infections. (Refer to CP: Acquired Immunodeficiency Syndrome [AIDS] for information.)
- III. Etiology**
- Infection results from one of two similar retroviruses—HIV-1 and HIV-2—that destroy CD4 lymphocytes and impair cell-mediated immunity, thereby increasing the risk of certain infections and cancers. *Note:* Currently, HIV-1 is the predominant subtype that causes HIV/AIDS (Gompf, 2017; HIV.gov, 2017a; U.S. Department of Health and Human Services [DHHS], 2017a).
  - Mode of transmission (DHHS, 2017b; Gompf, 2017; HIV.gov, 2017a)
    - HIV is spread through contact with the blood, semen, preseminal fluid, rectal fluids, vaginal fluids, or breast milk of a person with HIV.
    - In the United States, HIV is spread mainly by having anal or vaginal sex or sharing drug injection equipment with a person who has HIV.
    - Mother-to-baby perinatal transmission and through breastfeeding: In 2016, 76% of all HIV-positive women
- (globally) received medicines to prevent HIV transmission to their babies (World Health Organization [WHO], 2016). The annual number of HIV infections through perinatal transmission has declined by more than 90% since the early 1990s (Centers for Disease Control and Prevention [CDC], 2017c).
- iv. High-risk populations—Globally, more than 11 million people were incarcerated in prisons in 2016. Overrepresented among this population are the people most vulnerable to HIV, including people who use drugs, sex workers, men who have sex with men, transgender people, and others who are most marginalized in communities (WHO, 2017).
- IV. Statistics**
- Morbidity:** In 2015, there were an estimated 36.7 million people worldwide with HIV (HIV.gov, 2017b). In the United States at the end of 2016, an estimated 1.1 million persons aged 13 and older were living with HIV infection (CDC, 2017e). In 2014, the estimated number of *new* HIV infections in the United States was 39,782, with the highest number being in the age group 25 to 29 years, and with gay and bisexual men accounting for 67% of all HIV diagnoses (CDC, 2017d).
  - Mortality:** Associated with progression to AIDS; however, research shows that if highly active antiretroviral therapy (HAART) medications are taken early and correctly, life expectancy can increase by about 30 to 40 years from what it was in the past. This increase in life expectancy has occurred in the past decade, meaning that people living with HIV/AIDS, in countries where the HAART treatment is available, can expect to live roughly two-thirds of a normal life span (Stibitch, 2017).
  - Cost:** According to the Kaiser Family Foundation (KFF), in 2016, the U.S. federal government spent a total of \$26.4 billion on HIV care (KFF, 2017).

## G L O S S A R Y

- Acquired immunodeficiency syndrome (AIDS):** Most severe stage of HIV infection.
- Acute retroviral syndrome (ACR):** Describes a group of symptoms that can resemble mononucleosis—fever, fatigue, muscle aches, loss of appetite, upset stomach, and weight loss.
- CD4:** Type of protein molecule in the blood that is present on the surface of immune cells. The HIV virus infects cells that have CD4 surface proteins and, as a result, depletes the number of T cells, B cells, natural killer cells, and monocytes in the blood. Most of the damage to the immune system is through destruction of CD4 lymphocytes.
- Electrophoresis:** Method of separating large molecules, such as DNA fragments or proteins, from a mixture of similar molecules.
- Herpes simplex virus (HSV-2):** Virus that has deleterious effects with coinfection of HIV.

**Human immunodeficiency virus (HIV):** Virus that causes a progressive disease leading to AIDS.

**Seroconversion:** Development of an antibody response to infection that is measurable in the serum.

**Sexually transmitted infections (STIs):** Group of infections that can be transferred from one person to another through sexual contact (vaginal, anal, oral); includes chlamydia, syphilis, herpes, genital warts, and gonorrhea, among others.

**T cells:** Lymphocytes that originate in the thymus gland and regulate the immune system's response to infections, including HIV; CD4 lymphocytes are a subset of T lymphocytes.

**Thrush:** Fungal infection of the mucous membranes appearing as a patchy, raised white rash or spots.

**Viral load tests:** Detects viral RNA levels as low as 50 copies.

## CARE SETTING

Client is treated in a community setting, although development of opportunistic infections may require occasional inpatient acute medical care.

## RELATED CONCERNs

Acquired immunodeficiency syndrome (AIDS), page 800  
Extended/long-term care, page 896  
Psychosocial aspects of care, page 835

## CLIENT ASSESSMENT DATABASE

Although client may be asymptomatic, refer to CP: Acquired Immunodeficiency Syndrome (AIDS) for potential signs and symptoms. Refer to section at end of plan for ongoing considerations.

DIAGNOSTIC STUDIES		
TEST	WHY IT IS DONE	WHAT IT TELLS ME
<b>BLOOD TESTS</b>		
• <b>Nucleic acid test (NAT):</b>	Looks for actual HIV virus in the blood.	This test can give either a positive/negative result or a numerical value of virus present in the blood (HIV viral load). Can usually detect virus from 33 to 90 days after exposure. It is not used for screening individuals unless they recently had a high-risk exposure or a possible exposure and with early symptoms of HIV infection (CDC, 2017e).
• <b>Rapid HIV screening tests (e.g., OraQuick Rapid HIV-1 or HIV-2 Antibody Test or home blood test kit):</b>	Oral or fingerstick blood test that screen for HIV antibodies.	These screening tests can provide negative or positive results in a short period of time. <i>Note:</i> In clinical studies by the manufacturer, OraQuick correctly identified 99.6% of people who were infected with HIV-1 (sensitivity) and 100% of people who were not infected with HIV-1 (specificity). A negative screening test may need to be repeated in a few months. A positive test must be followed up with more specific testing (U.S. Food and Drug Administration [FDA], 2015).
• <b>HIV antibody/antigen combination test/fourth-generation duo antibody/antigen test:</b>	Checks for HIV antibodies and HIV antigen (protein called p24 that's part of the virus) in the blood.	Antibodies to HIV can be detected in the blood about 2 to 4 weeks after exposure to the virus. <i>Note:</i> The fourth-generation test detects HIV antibodies as well as p24 antigens. Serum concentrations of p24 antigens are high in the first few weeks after infection; therefore, they are useful in diagnosing very early HIV infections when antibody levels are still low. A rapid HIV-1/2 Ag/Ab combo test can also tell whether an HIV infection is new or is established (HealthLabs.com, n.d.; Healthwise Staff, 2015).
• <b>Enzyme-linked immunosorbent assay (ELISA):</b>	Sensitive immunoassay that uses an enzyme linked to an antibody or antigen as a marker for the detection of a specific protein.	This test is often the first one used to detect infection with HIV because it can detect antibodies in 2 to 4 days. If antibodies to HIV are present, the test is usually repeated to confirm the diagnosis. If ELISA is negative, other tests may not be needed (Healthwise Staff, 2015).
• <b>Western blot test:</b>	Technique for identifying specific antibodies or proteins in which proteins are separated by electrophoresis.	Confirms diagnosis of HIV-1 in individuals with two positive ELISA screening tests. Results can typically be obtained in 1 to 2 weeks.
<b>VIRAL LOAD TESTS</b>		
• <b>Polymerase chain reaction (PCR):</b>	Highly sensitive technique for detecting and quantifying viral load.	Detects either the RNA of the HIV virus or the HIV DNA in white blood cells (CD4+ cells, part of the body's immune system). <i>Note:</i> The PCR test is useful to find a very recent infection, determine if an HIV infection is present when antibody test results were uncertain, and screen blood or organs for HIV before donation (Healthwise Staff, 2015).
• <b>Lymphocytes</b>		About 15% to 40% of white blood cells are lymphocytes, which (1) protect from viral infections, (2) help other cells fight infections, (3) produce antibodies, (4) fight cancers, and (5) coordinate the activities of other cells in the immune system. Lymphocytes include the CD4 and CD8 cells.

(continues on page 788)

## DIAGNOSTIC STUDIES (contd.)

WHY IT IS DONE (continued)	WHAT IT TELLS ME (continued)
<ul style="list-style-type: none"><li><b>CD4 cells (also called T4 helper cells):</b> CD4 cells are the prime target for HIV infection and destruction.</li></ul>	A normal CD4 count is from 500 to 1400 cmmL of blood. CD4 counts decrease over time in persons who are not receiving antiretroviral therapy. At levels below 200 cells per cubic millimeter, client becomes susceptible to a wide variety of opportunistic infections.
<ul style="list-style-type: none"><li><b>CD8 cells (also called T8 or suppressor T cells):</b> White blood cells that kill cells infected with viruses.</li></ul>	The CD8 count is elevated but is not as useful a marker as the CD8 percentage, which tends to vary less between measurements.
<ul style="list-style-type: none"><li><b>CD-cell ratio:</b> CD4 divided by CD8 count.</li></ul>	A normal ratio is usually between 0.9 and 6.0. Most experts agree that once antiretroviral treatment is started, an increase in the CD-cell ratio (i.e., a rising CD4 count and a falling CD8 count) is a sign that treatment is working (POZ, 2016b).

## OTHER DIAGNOSTIC STUDIES

- Pap smear:** Detects precursor lesions that can precede the diagnosis of invasive carcinoma.
- Pelvic/genital examination:** Direct visualization of structures and mucosal membranes.
- Chest x-ray:** Procedure used to evaluate organs and structures within the chest for symptoms of disease.

Higher incidence of abnormal cells occurs in HIV-infected women.  
Identifies presence of lesions from STIs and may trigger HIV testing.  
Abnormalities suggest presence of TB, which is common with HIV infection, or other opportunistic infections.

## NURSING PRIORITIES

- Promote acceptance of reality of diagnosis and condition.
- Support incorporation of behavioral and lifestyle changes to enhance well-being.
- Provide information about disease process, prognosis, and treatment needs.
- Assist in developing plan and strategies to meet long-term medical, behavioral, and financial needs and enhancing quality of life.

## GOALS OF ONGOING CARE

- Dealing with current situation realistically.
- Participating in and appropriately managing therapeutic regimen.
- Diagnosis, prognosis, and therapeutic regimen understood.
- Plan in place to meet medical, behavioral change, and financial needs.

## NURSING DIAGNOSIS: risk-prone Health Behavior

### May Be Related To

Inadequate comprehension; low self-efficacy  
Stressors; insufficient social support; economically disadvantaged  
Negative perception of healthcare provider/recommended healthcare strategy

### Possibly Evidenced By

Minimizes or nonacceptance of health status change; failure to take action that prevents health problem  
Substance misuse

### Desired Outcomes/Evaluation Criteria—Client Will

#### Acceptance: Health Status NOC

Verbalize reality of condition.  
Demonstrate increased trust and participation in development of plan of action.  
Initiate lifestyle changes that will permit adaptation to present life situations.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Crisis Intervention NIC</b>	
<b>Independent</b>	
Evaluate client's ability to understand events and realistically appraise situation.	Provides base to develop plan of action.
Identify real barriers to adjustment.	Promotes opportunity to deal appropriately with real problems in client's individual situation.
Encourage expression of feelings, denial, shock, and fears. Listen without judgment, accepting client's expressions. Focus on positive outcomes.	It is important to convey belief in client's fears and feelings. By focusing on positive outcomes, client is encouraged to take charge of those areas in which changes can be made, such as managing medical regimen and behavior.
Challenge morbid thoughts and reframe into positive statements: "You know why the virus is going to kill me. I deserve to die for what I've done." Response: "The virus may or may not kill you. It's not smart enough to decide when you may die. The virus is 'just there.' It does not have a mind to know what you have or have not done."	Interrupts morbid thoughts and challenges client's self-deprecating ideas. As with any potentially terminal disease, this population is likely to experience depression and is at increased risk for suicide, necessitating ongoing evaluation.
Determine available resources and programs.	Identifies client needs and what comprehensive services might be available and immediately accessible. Services may include education concerning sexual myths, HIV transmission prevention, safer sex practices, and alternate methods of expressing sexuality. Interventions and education may be needed for addictive behaviors, such as the ability of injection drug user to obtain clean "works."
Assess social system as well as presence of support, perception of losses, and stressors.	Partners, friends, and families will have individual responses depending on the individual's lifestyle, knowledge of HIV transmission, and belief systems. Note: Belief systems can include values or myths, which affect how the individual approaches the disease and the outcome.
Encourage client to participate in support groups.	Long-term support is critical to dealing with and effectively coping with the reality of being HIV positive and with frequent healthcare evaluations, medical treatments, and ongoing lifestyle changes.
Educate client about drug interactions, HIV, and emotions.	Fatigue and depression can be side effects of some medications and of the infection itself. Knowledge that these effects are usually of short duration can support informed choices and cooperation and promote hope.
Encourage continued or renewed use of familiar effective coping strategies.	Client is supported and given encouragement for past effective behaviors. Positive reinforcement enhances self-esteem.
Explore use and practice of new and different coping strategies.	Using new strategies is uncomfortable in the beginning, but practice fosters self-confidence.
Help client use humor to combat stigmatization of the disease.	Humor defuses the sense of secretiveness people may place on diagnosis of, and dealing with, HIV.
Reinforce structure in daily life. Include exercise as part of routine.	Routines help the client focus. Exercise improves sense of wellness and enhances immune response.
Discuss meaning of high-risk behavior, such as unprotected sexual activity, injection drug use with shared needles, and failure to take antiretroviral medications, and address barriers to change.	Fear of disclosure, need to change usual behaviors, and the difficulty of doing so may prevent the individual from making the changes necessary to prevent transmission of disease and to manage lifestyle.
Assist client to set limits on sexually risky behaviors and explore ways client can achieve change.	Needs for love, comfort, and companionship that are met through sexual expression must be met safely through means that carry a reduced risk of HIV transmission.
Assist client to channel anger to healthy activities.	The increased energy of anger can be used to accomplish other tasks and enhance feelings of self-esteem.

(continues on page 790)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Inform client about new medical advances and treatments. Discuss issues of voluntary disclosure, personal responsibility, needs of others, and federal, state, and local reporting requirements.	Promotes hope and helps client make informed decisions. Understanding responsibilities and consequences of disclosure is necessary for client to make informed decisions.
<b>Collaborative</b> Refer client to nurse practitioner or clinical nurse specialist, psychologist, or social worker knowledgeable about HIV as well as specific HIV programs and resources or appropriate research programs.	Trained professionals can help client adjust to difficult situation.

## NURSING DIAGNOSIS: Fatigue

### May Be Related To

Illness; malnutrition; physical deconditioning  
Stressors, anxiety; depression

### Possibly Evidenced By

Tiredness; lethargy; nonrestorative sleep pattern; increase in physical symptoms, rest requirements  
Insufficient energy; impaired ability to maintain usual routines or physical activity  
Ineffective role performance; alteration in concentration; disinterest in surroundings; introspection

### Desired Outcomes/Evaluation Criteria—Client Will

#### Fatigue Level NOC

Report improved sense of energy.  
Participate in desired activities at level of ability.  
Participate in recommended treatment program.

#### Energy Conservation NOC

Identify individual areas of control and engage in energy conservation techniques.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Energy Management NIC</b> <i>Independent</i> Obtain client/SO descriptions and rating (using numerical scale) of fatigue. Note presence of additional concerns (e.g., irritability, lack of concentration, relationship difficulties).	Helps to evaluate impact of fatigue on client's quality of life and identify areas that are exacerbating low energy. Note: A recent study reported that fatigue affects nearly 90% of people living with HIV and has been reported as one of the most persistent and troubling symptoms they experience. An elevated risk of fatigue may be related to hematologic and metabolic changes (direct results of HIV infection and treatment), as well as psychological and psychosocial stressors (Barroso et al, 2015).
Assess sleep patterns and other factors that may be aggravating fatigue.	Multiple factors can cause and aggravate fatigue, including sleep deprivation, emotional distress associated with diagnosis, side effects of drugs, or developing HIV-related complications.
Encourage evaluation of fatigue when antiretroviral treatment is initiated or medications have been added to regimen.	Fatigue is present in variable degrees as part of HIV infection process but is often aggravated by nutritional deficiencies and side effects of certain medications. Even though anti-HIV drugs may improve energy levels, some may also cause fatigue. Tiredness, fatigue, insomnia, and sleep disturbances are possible side effects of several anti-HIV drugs. Side effects are most common in the first few weeks after starting HIV treatment, or when protease inhibitors (PIs) are added or changed, fatigue may worsen.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Discuss reality of client's feelings of exhaustion and identify limitations imposed by fatigue state. Advise client to maintain a fatigue diary, and note daily energy patterns—peaks and valleys.	Helpful in planning activities within tolerance levels. Clients often expect too much of themselves, believing that they should be able to do more.
Assist client to set realistic activity goals, determining individual priorities and responsibilities.	Client may need to alter priorities and delegate some responsibilities to manage fatigue and optimize performance.
Discuss energy conservation techniques, such as sitting instead of standing for activities, as appropriate.	Enables client to become aware of ways in which energy expenditure can be maximized to complete necessary tasks.
Review importance of meeting individual nutritional needs.	Adequate nutrition is needed for optimizing energy production. (Refer to ND: imbalanced Nutrition: less than body requirements, following.)
Encourage adequate rest periods during the day, routine schedule for bedtime and arising, and scheduling activities during time of best energy.	Helps client recoup energy to manage desired activities.
Instruct in stress management techniques, such as breathing exercises, visualization, and music and light therapy.	Reduction of stress factors in client's life can minimize energy output.
Identify available resources and support systems.	May require outside assistance with many things, including homemaking and maintenance activities and child care.

### NURSING DIAGNOSIS: imbalanced Nutrition: less than body requirements

#### May Be Related To

Insufficient dietary intake; inability to ingest/digest food  
Economically disadvantaged

#### Possibly Evidenced By

Weight loss; insufficient muscle tone  
Food intake less than recommended daily allowance (RDA)  
Food aversion; alteration in taste sensation; sore buccal cavity  
Insufficient information; misperceptions  
Abdominal cramping; diarrhea  
[Abnormal laboratory studies (e.g., vitamins, minerals, protein deficiency, electrolytes)]

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Nutritional Status NOC

Maintain stable weight.  
Report improved energy level.

##### Nutritional Status: Biochemical Measures NOC

Demonstrate laboratory values within normal limits.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Nutrition Management NIC</b> <i>Independent</i> Determine usual weight before client was diagnosed with HIV.	Early wasting is not readily determined by normal weight-to-height charts; therefore, determining current weight in relation to prediagnosis weight is more useful. Recent unexplained or involuntary weight loss may be a factor in seeking initial medical evaluation.
Weigh regularly and establish current anthropometric measurements. Measure resting energy expenditure (REE) using indirect calorimetry.	Helps assess and monitor wasting and determine nutritional needs. Indirect calorimetry is more accurate for calculating REE than the Harris-Benedict equation, which underestimates the energy needs of these clients.

(continues on page 792)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Determine client's current dietary pattern and intake and knowledge of nutrition. Use an in-depth dietary assessment tool.	Identification of these factors helps plan for individual needs. Clients with HIV infection have documented vitamin (e.g., vitamin B <sub>12</sub> , folate) and trace mineral (e.g., zinc, magnesium, selenium) deficits. Alcohol and drug abuse can interfere with adequate intake.
Assess presence and degree of nausea and vomiting.	The causes of nausea and vomiting are numerous and are associated with medications, functional changes in gastrointestinal (GI) system, and endocrine dysfunction. Note: Protracted nausea and vomiting can debilitate a client, leading to loss of lean body mass, electrolyte imbalances, and further deterioration of immune function.
Ascertain current financial status and recent and/or anticipated changes in economic status. Explore related costs of a variety of foods.	Helps in planning for meeting nutritional needs, such as purchasing low-cost foods that are nutritionally rich. Client may need referral to financial aid, such as Supplemental Nutrition Assistance Program (SNAP), to help with food stamps or obtaining meals.
Help client plan ways to maintain/improve intake. Identify lactose-free supplements, as appropriate. Provide information about nutritionally dense high-calorie, high-protein, high-vitamin, and high-mineral foods.	Having this information helps client understand importance of a well-balanced diet. Some clients may try macrobiotic and other diets, believing diarrhea is caused by lactose intolerance. Eliminating dairy products can have detrimental effects when these nutrient components are not replaced from other sources.
Emphasize importance of maintaining balanced, adequate nutritional intake and fluids rich with electrolytes, such as Gatorade, Powerade, Smart Water.	Client may be depressed and discouraged by changed health and social status and find it difficult to eat for many reasons. Knowing how important nutritionally balanced intake is to supporting the immune system and remaining healthy can motivate client to eat.
Assist client to formulate dietary plan, taking into consideration increased metabolic demands, energy needs, and hyperlipidemia.	Provides guidance and feedback while promoting sense of control, enhancing self-esteem, and possibly improving intake. HIV infection is continuously stimulating the immune system, increasing metabolic rate and nutritional needs. Note: Use of PIs is known to elevate levels of glucose and lipids—especially triglycerides and cholesterol.
Recommend eating frequent, small meals, avoiding cooking odors if bothersome, keeping room well ventilated, and removing noxious stimuli. Suggest use of spices, marinating red meat before cooking, and/or substituting other protein sources for red meat.	Reduces possible adverse stimuli or enhances palatability of food and may improve nutritional intake, which is needed to help client restore and maintain nutritional defenses.
Recommend environment conducive to eating. Emphasize importance of sharing mealtime with others. Identify someone who can join client for meals.	A quiet, relaxed, calm, unrushed setting and socialization can enhance appetite/food intake, especially when depression, neglect of self-care, and diminished appetite are present.
Explore complementary therapies and nonpharmacological interventions, such as acupressure, progressive relaxation, and guided imagery, to manage anorexia.	The goal of these interventions is to manage distressing symptoms that interfere with optimal nutritional intake.
Discuss and document nutritional side effects of medications.	Commonly used medications cause anorexia, altered taste, nausea and/or vomiting; some interfere with bone marrow production of RBCs, causing anemia. PIs increase the risk of developing diabetes. GI symptoms are common with over-the-counter (OTC) drugs, such as nonsteroidal anti-inflammatory drugs (NSAIDs), which may also contribute to anorexia.
Discuss use of <i>Lactobacillus acidophilus</i> replacement, such as LactAid dairy products, tablets, or capsules.	HIV infection changes the structure of the gut wall, resulting in a decreased lactose level. Intolerance causes abdominal cramping, malabsorption, a bloated feeling, and diarrhea. Also, antibiotics taken for prevention of opportunistic infections cause changes in normal bowel flora, contributing to diarrhea.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<b>Collaborative</b> Consult with dietitian and nutritional support team.	Provides assistance in planning nutritionally sound diet and identifying nutritional supplements to meet individual needs. Liquid supplements (e.g., Advera) have been specifically formulated for the GI manifestations common to the HIV-positive population.
Monitor laboratory values, such as Hgb, RBCs, albumin or prealbumin, total iron-binding capacity (TIBC), potassium, and sodium.	These laboratory tests are important in monitoring the client's nutritional immune status and in identifying nutritional therapy needs. For example, anemia may require additional interventions, such as use of epoetin (Epogen or Procrit), to stimulate RBC production.
Provide medications, as indicated, for example:  Dronabinol (Marinol), megestrol (Megace), and cyproheptadine (Periactin)	Antiemetics or appetite stimulants can improve intake to prevent and correct dietary deficiencies. Note: A side effect of Megace may include impotence, necessitating change of drug as desired.
Antidiarrheal medications, such as diphenoxylate/atropine (Lomotil) and octreotide (Sandostatin)	Diarrhea may be present because of altered GI flora and side effects of anti-infective agents. Treatment can correct malabsorption and enhance oral intake.

<b>NURSING DIAGNOSIS:</b> <b>deficient Knowledge regarding disease, prognosis, treatment, self-care, and discharge needs</b>
<b>May Be Related To</b> Insufficient information; insufficient interest in learning; misinformation presented by other Alteration in cognitive functioning or memory Insufficient knowledge of resources
<b>Possibly Evidenced By</b> Insufficient knowledge Inaccurate follow-through of instructions; development of preventable complications
<b>Desired Outcomes/Evaluation Criteria—Client Will</b>
<b>Knowledge: Chronic Disease Management NOC</b> Verbalize understanding of condition, disease process, and potential complications. Identify relationship of signs and symptoms to the disease process and correlate symptoms with causative factors. Verbalize understanding of goals of treatment. Initiate necessary lifestyle changes. Participate in treatment regimen.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Learning Facilitation NIC</b> Assess emotional and intellectual ability to assimilate information and understand instructions. Respect client's need to use denial and coping techniques initially.	Initial shock and anxiety can block intake of information. Self-esteem, lifestyle, guilt, and denial of own responsibility in acquiring or transmitting disease become issues that must be dealt with. Note: Some initial denial may serve as a protective mechanism promoting more effective self-care.
Provide realistic, optimistic information during each contact with client.	Necessary to provide realistic hope because many clients have been exposed to some inaccurate information about AIDS or may have friends or lovers who have died of the disease.
Plan frequent short sessions for teaching. Include written information, as appropriate—a few pieces at each visit.	Client will likely feel overwhelmed and need time and repeated contacts to absorb information, the scope of, and the requirements for treating the infection. Written materials allow for later review and reinforcement of information presented.

(continues on page 794)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Include significant other (SO) and family in discussions and conferences, as appropriate.	Provides opportunity to learn information firsthand, ask questions, and provide support for client.
<b>Teaching: Disease Process NIC</b>	
Determine current understanding and perception of diagnosis. Discuss difference between HIV-positive status and AIDS.	Provides opportunity to clarify misconceptions and myths and make informed choices. People often believe that if they are positive for the virus, they have AIDS; having accurate information about the difference can alleviate fears and allow for development of an individualized plan of care.
Identify and problem-solve potential or actual barriers to accessing healthcare services.	Transportation, distance, child care, work schedule, homelessness, poverty, and lack of insurance or finances are some of the issues that typically interfere with accessing needed primary care and prophylactic interventions.
Provide information about normal immune system response and how HIV affects it, transmission of the virus, behaviors, and factors believed to increase probability of progression. Encourage questions.	Client needs to be aware of own personal risk and risk to others to make immediate and long-range decisions and establish a basis for goal setting. Also, establishes rapport and provides opportunity to identify concerns and assimilate information.
Review signs and symptoms that could be a consequence of HIV infection—mild fever, anorexia, weight loss, fatigue, night sweats, diarrhea, dry cough, rashes, headaches, and sleep disturbances.	Client may experience an acute illness 2 to 6 weeks after becoming infected; however, it is common for infection to be subclinical, with the individual simply feeling unwell.
Discuss management strategies for persistent signs and symptoms.	Client involvement in care increases cooperation and satisfaction with care.
Identify signs and symptoms that require medical evaluation—persistent fever, increasing cough, swollen lymph glands, profound fatigue unrelieved by rest, weight loss of 10 pounds or more in less than 2 months, severe or persistent diarrhea, blurred vision, skin discoloration or rash that persists or spreads, open sores anywhere, and symptoms occurring with medication regimen.	Early recognition of progression of disease and development of opportunistic infections provides for timely intervention and may prevent situations that are more serious. Note: Most HIV-positive clients are on medication regimens (usually one to three drugs) and must adhere to the dosages and schedules, which may be difficult and/or cause side effects that tempt client to alter or discontinue them without notifying the physician.
Emphasize necessity of regular follow-up care and evaluations, including routine CD4 and HIV-RNA viral load counts, and any change in medication regimen, including time, frequency, and side effects.	Even though client may be asymptomatic, periodic evaluation may prevent development of complications, slow the progression of the disease, and assist with treatment decisions. Note: Clients who change medication dosage and/or frequency in response to side effects can create problems for medication adjustment later with increased viral load and drug resistance.
Discuss need for regular gynecological examinations.	HIV-positive women experience a high prevalence of Pap smear, vaginal, and cervical abnormalities.
Discuss family planning issues and careful selection of oral contraceptives.	Various antiretroviral drugs have differing effects on ethinyl estradiol (EE), either enhancing or decreasing protective effectiveness.
Provide preconception counseling, giving information about risk of vertical transmission and ways to reduce the possibility of perinatal transmission.	The risk of viral rebound with adverse consequences to the fetus increases in women currently receiving treatment at the time of conception. Research shows that when antiretroviral treatment is initiated early in pregnancy, the perinatal transmission rate is less than 1%.
Refer to Antiretroviral Pregnancy Registry, as appropriate.	National and international research is ongoing on the safety of highly active antiretroviral therapy (HAART) for HIV-positive pregnant woman. In 2012, new practice guidelines for antiretroviral therapy (ART) during pregnancy were federally approved in the United States. Updates in 2016 still recommend that pregnant HIV-infected women should receive a combination ART regimen regardless of plasma RNA copy numbers or CD4

**ACTIONS/INTERVENTIONS (continued)****RATIONALE (continued)****Teaching: Prescribed Medication NIC**

Discuss recommended HIV treatment (depends on multiple factors, including stage of HIV infection, client's willingness or desire to enter into/adhere to treatment), and address ways to optimize adherence to treatment plan.

Review drug therapies, including correct dosing and scheduling, side effects, monitoring tests and techniques, and adverse reactions as appropriate.

Fusion (or Entry) inhibitors (e.g., enfuvirtide [Fuzeon], maraviroc [Selzentry])

Integrase inhibitors (INSTIs) (e.g., elvitegravir [Vitekta], raltegravir [Isentress], dolutegravir [Tivicay])

HIV drug boosters (e.g., ritonavir [Norvir], cobicistat [Tybost])

Nucleoside and nucleotide reverse transcriptase inhibitors (NRTIs/NtRTIs): (e.g., emtricitabine [Emtriva], lamivudine [Epivir], zidovudine [Retrovir], didanosine [Videx EC], tenofovir [Viread], stavudine [Zerit])

Protease inhibitors (PIs) (e.g., atazanavir [Reyataz], darunavir [Prezista], fosamprenavir [Lexiva], indinavir [Crixivan])

count to prevent mother-to-child transmission of HIV and to protect their own health. The choice of regimen reflects current adult treatment guidelines, taking pregnancy-safe drug recommendations into consideration (DHSS, 2017c). A woman must be counseled prior to initiating therapy. Benefits versus risks, including effects on fetus, must be weighed, especially if regimen is started in first trimester.

HIV is a lifelong chronic disease, but it is treatable and can be controlled with medications. It is important that HIV-positive client is educated on the benefits and risks of antiretroviral (AVR) therapy. Initiating treatment is not based solely on viral load or CD4 count but rather on three major goals: (1) treating HIV before the virus has had a chance to cause serious damage to the immune system, (2) reducing risk of non-AIDS-related diseases that are becoming more common among people living with HIV (e.g., cardiovascular, kidney, and liver disorders), and (3) reducing the risk of transmitting the virus to others. Note: Viral load and CD4 count testing is used to monitor the effectiveness of therapy (POZ, n.d.).

Antiretroviral drugs are organized into five classes based on the stage of the HIV life cycle they block. Today, there are 27 individual agents and 12 fixed-dosed combination (FDC) drugs comprising two or more of different molecules. Seven of the FDCs, in fact, can be used as a single-pill, once-daily therapy, ensuring greater treatment adherence and ease of use (Myhre & Sifris, 2017; POZ, n.d.).

Fusion inhibitors stop HIV from merging with the cell membrane of certain cells of the immune system. This blocks HIV from getting into and infecting the cells. It prevents HIV from multiplying and can reduce the amount of HIV in the body (AIDSinfo, 2016).

These agents prevent HIV from integrating its genetic coding into the DNA of the infected host cell by blocking an enzyme called integrase and, by doing so, makes it impossible for HIV to replicate. Note: Current DHHS guidelines place INSTIs as preferred, first-line agents for persons newly diagnosed for HIV (Cichocki, 2017).

Drugs that can increase the plasma concentration of certain antiretroviral (AVR) agents when used in combination therapy. Allows prescriber to reduce the dosage and frequency of the ARV, while lowering the potential for drug-related side effects (Myhre & Sifris, 2016).

NRTIs block an HIV enzyme called reverse transcriptase (a protein that starts or increases the speed of a chemical reaction). By blocking reverse transcriptase, NRTIs prevent HIV from multiplying and can reduce the amount of HIV in the body.

Protease inhibitors block the activity of the protease enzyme, which HIV uses to break up large proteins into the smaller pieces required for assembly of new viral particles. When combined with NRTIs, PIs control the HIV-RNA viral load by blocking viral replication at two different target sites in the replication process. Immune function is maintained with early intervention or improved when initiated later.

(continues on page 796)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Nonnucleoside reverse transcriptase inhibitors (NNRTIs) (e.g., etravirine [Intelence], delavirdine [Rescriptor], nevirapine [Viramune], efavirenz [Sustiva])	NNRTIs bind to and block HIV reverse transcriptase (an enzyme) that HIV uses to convert its RNA into DNA (reverse transcription). This blocking prevents HIV from replicating. NNRTIs are used in combination to reduce possibility of drug resistance.
Discuss combination drugs and once-daily pills, such as elvitegravir-cobicistat + tenofovir + emtricitabine (Stribild), efavirenz + tenofovir + emtricitabine (Atripla), rilpivirine + tenofovir + emtricitabine (Complera) as indicated.	Teaching about drug regimen will be highly individualized, depending on the client's needs. Many clients may now be taking all-in-one combination pills once daily, especially when HIV has been diagnosed in early stages. Others may be on more complex regimens.
Provide information about clinical trials available, as individually appropriate.	Scientific research requires HIV-positive test subjects. Participation may provide individual with a sense of contributing to the body of knowledge or search for a cure in addition to no-cost monitoring and medications for those with limited financial resources.
Provide information about pharmaceutical company assistance programs.	Some medications are provided free or at reduced cost, based on income.
<b>Risk Identification NIC</b>	
Assess potential for inappropriate or high-risk behavior, such as continued injection drug abuse or unsafe sexual practices. Stress need to avoid use of illicit injected drugs or, if unwilling to abstain, to avoid sharing needles and to clean works with bleach solution, rinsing carefully with water.	High levels of denial, anger, or drug addiction may cause client to continue behaviors that are high risk for spread of the virus. Even moderate changes in lifestyle may reduce exposure to other infective agents that can cause additional stress to the immune system. Note: Client may intensify substance abuse as a means of denial. A sense of "not me" can contribute to continuation of risky behaviors.
Recommend exploring drug treatment resources—methadone clinics or substance abuse recovery groups or programs.	May help reduce risk of HIV transmission by reducing injection drug use when client substitutes methadone, recovers from drug use, or learns safer injection and needle use techniques.
Emphasize necessity of, and methods for, practicing safer sex at all times.	Limits spread of virus and exposure to other STIs. A person's sexual expression and identity are threatened by the discovery of the diagnosis. Therefore, many individuals with HIV will not reveal status to potential sexual partners, contributing to ongoing HIV transmission.
Discuss active changes in sexual behaviors that client can make that may satisfy sexual needs.	Learning alternative forms of expression promotes a sense of responsibility and control. Alternatives can reduce sexual tensions, promote normalcy in sexual relationships, and reduce fear or guilt related to potential transmission of HIV.
Provide information about other necessary lifestyle changes and health maintenance factors, such as:	Evidence suggests that specific dietary and lifestyle factors may slow the progression of HIV infection because they support a healthier immune system.
Avoid people with infections.	When the immune system is depressed, the person's ability to fight exposure to common communicable diseases is limited.
Exercise within ability, alternate rest periods with activity, and get adequate sleep.	Helps manage fatigue; maintains strength and sense of well-being. Exercise has also been shown to stimulate the immune system.
Eat regularly, even if appetite is reduced; try small, frequent meals and supplements and snacks high in nutritional value; and discuss ways to control nausea and vomiting and improve appetite.	Physical and psychological stressors increase metabolic needs; in addition, side effects of medication, presence of nausea or vomiting, and anorexia often limit oral intake. The result is nutritional deficits that can further impair the immune system.
Practice daily oral hygiene, use a soft toothbrush; examine mouth regularly for sores, white film, or changes in color; and have regular dental checkups every 6 months.	Poor oral hygiene and dental care can affect oral intake adversely and increase the risk of opportunistic and systemic infections.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Examine skin for rashes, bruises, and breaks in skin integrity.	May indicate developing complications and increase risk of infection.
Identify additional resources—support groups, peer counselors, mental health professionals, and case managers.	Client will experience a variety of emotional and psychological responses to the diagnosis and its consequences and may need additional assistance and periodic reinforcement to promote optimal adjustment. Note: In early stages of HIV infection, focus may be on social services (e.g., help with housing, employment, legal issues, and finances). Later, as disease progresses, the emphasis switches to medical and related community services.

NURSING DIAGNOSIS:	risk for Social Isolation
<b>Possibly Evidenced By</b>	
Illness	
Absence of support system; insufficient personal resources; withdrawal	
<b>Desired Outcomes/Evaluation Criteria—Client Will</b>	
<b>Social Support NOC</b>	Identify stable support system and supportive individual(s).
	Use resources for assistance, as appropriate.
<b>Loneliness Severity NOC</b>	Express sense of satisfaction with relationship(s).

ACTIONS/INTERVENTIONS	RATIONALE
<b>Support System Enhancement NIC</b>	
<i>Independent</i>	
Determine client's response to condition, feelings about self, concerns or fears about response of others, sense of ability to control situation, and sense of hope.	How the individual accepts and deals with the situation will help decide the plan of care and interventions.
Assess coping mechanisms and previous methods of dealing with life problems.	May reveal successful techniques that can be used in current situation.
Discuss concerns regarding employment and leisure involvement. Note potential problems involving finances, insurance, and housing.	Clients with this chronic, potentially terminal, illness face major problems with possible loss of employment, medical insurance, housing, and care sources if they become unable to independently care for themselves.
Identify availability and stability of support systems, including SO, immediate and extended family, and community.	This information is crucial to help client plan future care for a disease that carries a stigma and can negatively affect relationships.
Encourage contact with SO, family, and friends.	Many clients fear telling SO, family, and friends for fear of rejection, and some clients withdraw because of tumultuous feelings. Contact promotes sense of support, concern, involvement, and understanding. Supporting loved ones as they learn of the diagnosis is beneficial and can provide optimism for the long term.
Encourage honesty in relationships, as appropriate.	As a rule, acquaintances do not need to be informed of client's health status. However, information should be shared with close relationships such as SO, family, and current or potential sexual partners. Honesty can help identify stable support persons.
Assist client to problem-solve solutions to short-term and/or imposed isolations, such as communicable disease measures or severely compromised immune system.	Anticipatory planning can defuse sense of isolation and loneliness that can accompany these situations.

(continues on page 798)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Help client differentiate between isolation and loneliness or aloneness, which may be by choice.	Provides an opportunity for client to realize the control he or she has to make decisions about the choice to take care of self about these issues.
Be alert to verbal and nonverbal cues, such as withdrawal, statements of despair, and sense of aloneness. Determine presence and level of risk of suicidal thoughts.	Indicators of despair and suicidal ideation may be present. When these cues are acknowledged, client is often more willing to divulge thoughts and sense of isolation and hopelessness.
<b>Collaborative</b>	
Identify community resources, self-help groups, and rehabilitation or drug cessation programs, as indicated.	Provides opportunities for resolving problems that may contribute to sense of loneliness and isolation, transmission risks, and sense of guilt.
Refer to psychiatric clinical nurse specialist or psychiatrist, as needed.	May require more in-depth support to deal with feelings and manage difficult situations.

## NURSING DIAGNOSIS: **ineffective Health Management**

### May Be Related To

Difficulty managing complex treatment regimen, or navigating complex healthcare system  
Decisional conflict; perceived seriousness of condition, susceptibility, barriers, or benefits  
Family conflict; insufficient social support; powerlessness

### Possibly Evidenced By

Difficulty with prescribed regimens  
Failure to include treatment regimen in daily living or to take action to reduce risk factors  
Ineffective choices in daily living for meeting health goals  
[Unexpected acceleration of illness symptoms]

### Desired Outcomes/Evaluation Criteria—Client/Family Will

#### Self-Management: Chronic Disease **NOC**

Identify individual factors affecting management of regimen.  
Accept personal responsibility for own actions and participate in problem-solving activities.  
Develop contract for care with mutually agreeable goals for treatment and mechanisms for changing or terminating elements of plan.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Patient Contracting <b>NIC</b></b>	
<i>Independent</i>	
Make time to listen to client concerns.	Promotes feelings of value and may identify additional factors that affect outcome of therapy. Timing of teaching needs to consider the stage of acceptance.
Note client's stage of acceptance of the diagnosis:	
Precontemplation stage	Client has just learned of the diagnosis and may not be able to participate in any discussions.
Contemplation stage	Client can participate in, and may initiate, discussions of therapy. Encourages individual's responsibility to be involved with planning. Promotes increased sense of control and self-esteem.
Action or maintenance stage	Client is actively involved in understanding and managing own care.
Determine client's and SO's perception or understanding of regimen.	Identifies areas of confusion or conflict or lack of accurate information that may impede cooperation with regimen.
Assess perceived and actual barriers to accessing healthcare services and reasons for deviations from prescribed plan.	Provides opportunity to clarify actual problems and develop alternative plan acceptable to healthcare provider.
Instruct client carefully in all aspects of medication regimen, times, interaction with food, and side effects:	Thorough understanding may enhance cooperation with regimen and help in identifying potential for compromise.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Provide written schedule, if desired.	Helpful for keeping track of multiple drugs and changes that occur.
Recommend various methods to alert client to medication time, such as portable pill container or alarms.	Will assist busy or forgetful client to take medications at appropriate intervals.
Reduce dose frequency and number of pills when possible.	Increases ability to manage treatment regimen with little interference.
Emphasize importance of keeping healthcare providers informed of concerns and ability to continue prescribed medication regimen.	Drug levels quickly fall below therapeutic levels if one dose is missed. Reduces potential for drug resistance or increased viral load. Poor adherence or factors leading to discontinuation of an antiretroviral medication can impede future attempts to reduce viral load. Suboptimal drug exposure increases the potential for drug resistance.
Assist client to develop realistic health goals and incorporate wellness activities and practices—exercise, smoking cessation, nutrition, vitamin supplements—into daily routine.	Multiple responsibilities and demands on the client's time, especially with women, make it appear difficult to include any additional activities of self-care.
Provide anticipatory guidance and possible choices, if any, to prevent or delay complications.	Provides opportunity for client to prepare for expected changes and may permit earlier intervention.
Identify adaptive interventions valid for progressive long-term care needs.	Builds on coping strategies already effective for this individual.
Monitor adherence to prescribed medical regimen. Alter plan of care as needed.	Regimen is likely to be complicated and time-consuming. Thoughtful changes in plan may help enhance cooperation.
<b>Support System Enhancement NIC</b>	
Identify potential or actual support person(s). Include in teaching and problem-solving activities, as appropriate.	Helpful in planning for future and current needs of client and family.
Help client develop strategies that can gain supportive persons.	The more support persons there are available, the lower the risk of support burnout.
<b>Collaborative</b>	
Identify appropriate women's groups and services, social worker, financial resources, respite care, and other community programs.	Often female clients are single parents and caretakers for family. Groups can provide support and tangible help in dealing with issues of child care, parenting, and what to do when client is too ill to parent.
Refer to counselor, therapist, or spiritual advisor, as appropriate.	Opportunity to discuss concerns and fears may aid in problem-solving solutions and living with required changes.

**POTENTIAL CONSIDERATIONS** (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

- **Fatigue**—disease state; stress; depression
- **imbalanced Nutrition: less than body requirements**—inability to ingest/digest food; insufficient finances
- **Decisional Conflict**—unclear personal values or beliefs; perceived threat to value system; multiple or divergent sources of information; support system deficit; interference with decision making
- **risk for Infection**—chronic disease; suppressed inflammatory response; malnutrition
- **ineffective Health Management**—complexity of healthcare system or therapeutic regimen; perceived seriousness and susceptibility, or benefits of therapy; family conflicts or crises

# ACQUIRED IMMUNODEFICIENCY SYNDROME (AIDS)

## I. Pathophysiology

- a. AIDS is the most advanced stage of the human immunodeficiency virus (HIV) infection (stage 3) (HIV.gov, 2017a).
- b. Progression from HIV infection to AIDS is highly variable.
- c. AIDS (in adults) is defined as the presence of HIV infection with at least one other criterion:
  - i. Person with HIV must have an AIDS-defining condition (opportunistic infections and cancers that are life-threatening in a person with HIV), or
  - ii. Have a CD4 count less than 200 cells/mm<sup>3</sup>, regardless of whether the person has an AIDS-defining condition.
- d. Without treatment, people who progress to AIDS typically survive about 3 years.

## II. Etiology

- i. AIDS is an acquired complex of symptoms and infections caused by the HIV virus and may be the result of undiagnosed HIV, not taking antiretrovirals, drug resistance, or failure of antiretroviral therapy.
- ii. Opportunistic infections (OIs), while decreased in number, are still major contributors to morbidity and mortality in the HIV-infected client with advanced disease, especially for those who have not yet received anti-HIV therapy, as well as those for whom it has failed.
- iii. The pattern of opportunistic infections in a geographic region reflects the pathogens that are common in that area. For example, persons with AIDS in the United States tend to present with organisms such as *Pneumocystis* and *Candida* species (not a complete listing). Men having sex with men (MSM) are more likely to develop Kaposi's sarcoma because of coinfection with HHV-8. And TB, while on the rise, is more common in developing countries (Bennett & Gilroy, 2017a; Powderly, 2017; Selik et al., 2014).

iv. Research has revealed that certain infections are associated with particular CD4 counts. For example (Myhre & Sifris, 2017) [not a complete listing]:

1. CD4 counts from 500 to 250 cells/µL: candidiasis (especially of esophagus but also can affect bronchi, trachea, and lungs), Kaposi's sarcoma (KS) (pink or purplish skin lesions caused by the HHV-8 virus), TB (pulmonary or extrapulmonary; incidence rising globally)
2. CD4 counts from 250 to 100 cells/µL: *Pneumocystis jiroveci* pneumonia (PJP also called PCP); *Salmonella* (septicemia)
3. CD4 counts between 100 and 50 cells/µL: toxoplasmosis or HIV encephalopathy (dementia); cysitoisporiasis
4. CD4 counts under 50 cells/µL: cytomegalovirus (CMV), mycobacterium avium complex (MAC) (retinitis with vision loss; also severe diarrhea and ulcers), HIV wasting syndrome (profound weight loss accompanied by weakness and persistent diarrhea)

## III. Statistics

- a. Morbidity: As of 2015, an estimated 18,303 individuals were newly diagnosed with AIDS, and an estimated 521,002 persons were living with AIDS in the United States at the end of 2014 (CDC, 2016, 2017d).
- b. Mortality: Deaths of persons with diagnosed HIV infection ever classified as stage 3 (AIDS) may be due to "any cause." Using that classification, in 2015, the number of deaths in the United States ever classified as AIDS was 12,497. Deaths directly caused by HIV in 2014 were 6721 (CDC, 2017d).
- c. Cost: According to the Kaiser Family Foundation (KFF), in fiscal year (FY) 2017, the U.S. federal government spent a total of \$26.4 billion on HIV care (KFF, 2017).

## G L O S S A R Y

**AIDS-defining illnesses:** Group of over 20 conditions that, when coupled with a diagnosis of HIV, indicates the individual has progressed to AIDS. *Note:* While AIDS-defining illnesses can be classified as opportunistic infections, the opposite is not necessarily true. AIDS-defining illnesses, by contrast, tend to appear during later-stage disease when the CD4 count has dropped significantly. (See Opportunistic diseases below.)

**AIDS dementia complex (ADC):** Progressive mental disorder with different nervous system and mental symptoms—memory loss, speech problems, inability to concentrate, or poor judgment. There may be behavior changes, mood changes, and motor difficulties. ADC is considered an AIDS-defining condition in people with HIV. Also known as HIV-associated dementia.

**AIDS wasting syndrome:** AIDS wasting is the involuntary loss of more than 10% of body weight (fat and muscle mass), plus more than 30 days of either diarrhea or weakness and fever. Although the incidence of wasting syndrome has decreased dramatically since 1996, wasting

is still a problem for people with AIDS, even people whose HIV is controlled by medications.

**Antigen:** Substance that can stimulate the body to produce antibodies against it. Antigens include bacteria, viruses, pollen, and other foreign materials.

**Antiretroviral (ARV, also called ART):** Medication that interferes with the ability of a retrovirus (such as HIV) to make more copies of itself.

**Coinfection:** Infection with more than one virus, bacterium, or other micro-organism at a given time. For example, an HIV-infected individual may be coinfected with hepatitis C virus (HCV) or tuberculosis (TB).

**Combination therapy:** Two or more drugs used together to achieve optimal results in controlling HIV infection.

**Highly active antiretroviral therapy (HAART):** Aggressive anti-HIV treatment, using several antiretroviral drugs at one time. Also known as ART, ARV, and HART.

**Immunomodulators:** Drugs that strengthen the immune system and help the body to fight off infections or other diseases that attack people living with HIV/AIDS.

**G L O S S A R Y** (continued)

**Immunosuppression:** Inability of the immune system to function normally. May be caused by drugs, such as chemotherapy, or result from certain diseases, such as HIV infection.

**Opportunistic infections (OIs):** Opportunistic infections are those caused by otherwise common, harmless viruses, bacteria, fungi, or parasites that can cause disease when immune defenses have been compromised. Many opportunistic infections are not life-threatening and can develop even when a person's CD4 count is high. Some opportunistic infections, such as herpes simplex, are only AIDS-defining when they spread (disseminate) beyond the

tissue or organ where they are typically seen. (See AIDS-defining illness above.)

**Prophylaxis in HIV-infected client:** Primary prophylaxis is initiated at a stage when client is at risk of developing a particular infection (such as tuberculosis). Secondary prophylaxis (also called maintenance therapy) is initiated after appropriate treatment of the acute OI.

**Retrovirus:** Type of virus that stores its genetic information in a single-stranded RNA molecule, then constructs a double-stranded DNA version of its genes using a special enzyme called reverse transcriptase. The DNA copy is then integrated into the host cell's own genetic material.

**CARE SETTING**

The interventions listed here are appropriate for community care as well as an inpatient or hospice setting. Most of the signs and symptoms and psychosocial issues happen long before inpatient care.

**RELATED FACTORS**

Palliative/end-of-life care—hospice, page 970

Extended/long-term care, page 896

Fluid and electrolyte imbalances (see *DavisPlus*)

HIV-positive client, page 785

Psychosocial aspects of care, page 835

Sepsis/septic shock, page 772

**CLIENT ASSESSMENT DATABASE**

\*\*\*\*Data depend on the organs and body tissues involved, the current viral load, and the specific AIDS-related condition.

**DIAGNOSTIC DIVISION  
MAY REPORT****ACTIVITY/REST**

- Profound fatigue and malaise
- Weakness
- Altered sleep patterns

**CIRCULATION**

- Bruising or bleeding with minor injury
- Slow healing (if anemic)

**EGO INTEGRITY**

- Stress factors related to lifestyle changes—specifically healthcare planning and regimen of multiple medications—losses, including family support, relationships, independence, financial; spiritual concerns and change in self-concept (loss of control)
- Concern about appearance—hair loss, disfiguring lesions, weight loss, altered distribution of body fat associated with protease-inhibiting drug therapy, and wrinkling of skin
- Denial of diagnosis
- Feelings of hopelessness, helplessness, worthlessness, guilt, depression, and powerlessness

**MAY EXHIBIT**

- Muscle weakness, wasting of muscle mass
- Physiological response to activity—changes in blood pressure (BP), heart rate, and respirations

- Tachycardia, postural BP changes
- Decreased peripheral pulse volume
- Pallor or cyanosis
- Delayed capillary refill

- Denial, anxiety, depression, fear, and withdrawal
- Angry behaviors, dejected body posture, crying, and poor eye contact
- Failure to keep appointments or multiple appointments for similar symptoms

(continues on page 802)

**CLIENT ASSESSMENT DATABASE (contd.)****MAY REPORT (continued)****MAY EXHIBIT (continued)****ELIMINATION**

- Intermittent, persistent, frequent diarrhea that may last for more than a week at time with or without abdominal cramping
- Rectal pain, itching
- Flank pain, burning on urination

- Loose-formed to watery stools with or without mucus or blood; frequent, copious diarrhea
- Abdominal tenderness
- Incontinence
- Rectal, perianal lesions or abscesses
- Changes in urinary output, color, or character

**FOOD/FLUID**

- Anorexia, changes in taste of foods; food intolerance
- Nausea or vomiting
- Food intolerance—diarrhea after ingestion of dairy products, nausea, early satiation, or bloating
- Rapid, progressive weight loss
- Difficulty chewing and swallowing, retrosternal pain with swallowing (candidiasis of esophagus)

- Hyperactive bowel sounds
- Abdominal distention
- Thin frame, decreased subcutaneous fat or muscle mass
- Poor skin turgor
- Edema—generalized, dependent
- Lesions of the oral cavity, white patches, discoloration
- Poor dental and gum health, loss of teeth

**HYGIENE**

- Inability to complete activities of daily living (ADLs) independently

- Deficits in many or all personal care, self-care activities

**NEUROSENSORY**

- Changes in ability to solve problems, forgetfulness, poor concentration
- Impaired sensation or sense of position
- Muscle weakness, tremors
- Numbness, tingling in extremities
- Fainting spells and dizziness
- Changes in vision—light flashes or floaters, photophobia; blurred visions

- Mental status changes ranging from confusion to dementia, delirium with sudden onset
- Forgetfulness, poor concentration, decreased alertness, apathy, psychomotor retardation or slowed responses
- Paranoid ideation, free-floating anxiety, unrealistic expectations
- Abnormal reflexes, decreased muscle strength, ataxic gait
- Fine and/or gross motor tremors, focal motor deficits, hemiparesis
- Seizures
- Retinal hemorrhages and exudates (CMV retinitis); blindness

**PAIN/DISCOMFORT**

- Generalized or localized pain
- Headache
- Pleuritic chest pain

- Swelling of joints, painful nodules, tenderness
- Decreased range of motion (ROM)
- Gait changes, limp
- Muscle guarding

**RESPIRATION**

- Progressive shortness of breath
- Congestion or tightness in chest
- Cough ranging from mild to severe, nonproductive or productive of sputum; spasmodic cough on deep breathing (may be earliest sign of PCP)
- Frequent, persistent upper respiratory infections (URIs)
- History of exposure to or prior episode of active TB

- Tachypnea, respiratory distress
- Changes in breath sounds, presence of adventitious breath sounds
- Pneumonia

**SAFETY**

- Exposure to infectious diseases, such as TB or sexually transmitted infections (STIs)
- History of other immune deficiency diseases, such as rheumatoid arthritis, cancer

- Recurrent fevers, low-grade, intermittent temperature elevations or spikes, night sweats
- Nodules, enlarged lymph nodes in two or more areas of the body—neck, axillae, and groin, for example

MAY REPORT (continued)	MAY EXHIBIT (continued)
<ul style="list-style-type: none"> <li>Changes in skin integrity—cuts, ulcerations, rashes (eczema), exanthemas, psoriasis; discolorations; changes in size or color of moles; unexplained, easy bruising; multiple injection scars</li> <li>History of frequent or multiple blood or blood product transfusions; hemophilia, major vascular surgery, traumatic incident</li> <li>Suicidal or homicidal ideation with or without a plan</li> <li>Experiencing anger, disgust, rejection, and/or violence from others</li> </ul>	<ul style="list-style-type: none"> <li>Red, brown, pink, or purplish blotches on or under the skin or inside the mouth, nose, or eyelids</li> <li>Easy bruising, prolonged bleeding, and hemorrhage (thrombocytopenia)</li> </ul>
<b>SEXUALITY</b>	
<ul style="list-style-type: none"> <li>History of high-risk behavior, such as having sex with a partner who is HIV positive, multiple sexual partners, condomless sexual activity, and anal sex; substance use or abuse, injection drug user</li> <li>Loss of libido, too sick for sex, afraid to engage in any sexual activities</li> <li>Continued high-risk behavior (e.g., unchanged sexual behavior or injection drug use)</li> <li>Inconsistent use of condoms</li> </ul>	<ul style="list-style-type: none"> <li>Pregnancy or risk for pregnancy (sexually active), pregnancy resulting in HIV-positive infant</li> <li>Genitalia—herpes, warts, discharge</li> </ul>
<b>SOCIAL INTERACTION</b>	
<ul style="list-style-type: none"> <li>Problems related to diagnosis and treatment—loss of family/significant other (SO), friends, support; fear of telling others, fear of rejection; loss of income</li> <li>Isolation, loneliness, close friends or sexual partners who have died of, or are sick with, AIDS</li> <li>Questioning of ability to remain independent, unable to plan for needs</li> </ul>	<ul style="list-style-type: none"> <li>Changes in family or SO interaction pattern</li> <li>Disorganized activities, difficulty with goal setting</li> </ul>
<b>TEACHING/LEARNING</b>	
<ul style="list-style-type: none"> <li>Unaware of HIV infection</li> <li>Failure to comply with treatment</li> <li>Injection drug use or abuse, current smoking, alcohol abuse</li> </ul>	
<b>DISCHARGE PLAN CONSIDERATIONS</b>	
<ul style="list-style-type: none"> <li>Usually requires assistance with finances, medications and treatments, skin or wound care, equipment, supplies, transportation, food shopping and preparation, self-care, technical nursing procedures, homemaker and maintenance tasks, child care, and changes in living arrangements</li> </ul>	
<p>► Refer to section at end of plan for postdischarge considerations.</p>	

DIAGNOSTIC STUDIES	TEST WHY IT IS DONE	WHAT IT TELLS ME
<b>BLOOD TESTS</b>	<ul style="list-style-type: none"> <li>See <b>HIV-Positive Client Care Plan for Baseline HIV TESTs</b>, page 785</li> </ul>	(continues on page 804)

## DIAGNOSTIC STUDIES (contd.)

### WHY IT IS DONE (continued)

### WHAT IT TELLS ME (continued)

#### ADDITIONAL STUDIES

- **TB skin test/purified protein derivative (PPD):** Antigen used to aid in the diagnosis of TB infection.

- **Sexually transmitted infections (STI) screening tests:**

Lifestyle behaviors may increase risk of, or exposure to, infection by STIs.

- **Cytomegalovirus (CMV) serology**

Determines exposure to, or active, TB disease. Globally, TB is the leading cause of death among people who are HIV positive. From 1993 to 2015, the estimated percentage of HIV coinfection in persons with TB who reported HIV testing decreased from 63% to 8% among persons aged 25 to 44 years (CDC, 2017b). Note: It can be hard to diagnose TB in the HIV-infected client. If the immune system is very damaged, the tuberculin skin test (TST) may show negative, but TB disease can still be active. Chest x-ray and/or sputum tests may be needed to confirm TB diagnosis (Blahd, 2016).

Serology testing is done to evaluate for chronic infections (e.g., hepatitis B [HBV] hepatitis C [HVC], syphilis, and other common STIs [e.g., chlamydia, gonococcus]).

The presence of anti-CMV IgG indicates previous exposure to CMV. If test is positive in person with very low CD4 counts, an ophthalmic evaluation will be needed to evaluate for CMV retinitis (can result in blindness).

#### OTHER DIAGNOSTIC STUDIES

- **Monitoring blood studies (e.g., liver and kidney function tests, serum chemistries, CBC, lipids)**

Many different laboratory tests will be ordered depending on (1) stage of HIV infection, (2) presence and type of OIs, and (3) effects of AVR drugs on body systems

Done to identify the organism causing the OI and to determine best therapies.

- **Cultures:** Specific cultures (e.g., urine, blood, stool, spinal fluid, lesions, sputum, and secretions) may be done to identify causative organism(s). Sensitivity determines microorganism susceptibility or resistance to specific antimicrobials.

- **Neurological studies—electroencephalogram (EEG), magnetic resonance imaging (MRI), computed tomography (CT) scans of the brain, electromyography (EMG)/nerve conduction studies:** Indicated for persistent headache, changes in mentation, fever of undetermined origin, and/or changes in sensory or motor function.

Determines effects of HIV infection and/or OIs.

- **Chest x-rays:** Determines effects of disease process.

May initially be normal or may reveal progressive interstitial infiltrates secondary to *Pneumocystis jiroveci pneumonia* (PJP) (formerly known as *Pneumocystis carinii pneumonia* [PCP]), the most common OI and cause of death in the United States in persons with HIV infection (Bennett & Gilroy, 2017b). Other pulmonary complications can occur, such as TB, spontaneous pneumothorax, and hilar adenopathy.

Useful in early detection of interstitial pneumonias.

- **Pulmonary function tests:** Group of tests (e.g., spirometry, lung volumes, etc.) that measure how well the lungs take in and release air and how well they move oxygen into the blood.

May be done to identify OI (e.g., *Candida*, CMV) or to stage KS in the GI system.

- **Barium swallow, endoscopy, colonoscopy:** Tests for gastrointestinal (GI) function either by direct visualization or imaging studies.

May be done for differential diagnosis of KS or other neoplastic lesions.

- **Biopsies:** Determines presence of pathology and treatment options.

**NURSING PRIORITIES**

1. Prevent or minimize development of new infections.
2. Maintain homeostasis.
3. Promote comfort.
4. Support psychosocial adjustment.
5. Provide information about disease process, prognosis, and treatment needs.

**DISCHARGE GOALS/GOALS OF CARE**

1. Infection prevented or resolved.
2. Complications prevented or minimized.
3. Pain and discomfort alleviated or controlled.
4. Dealing with current situation realistically.
5. Diagnosis, prognosis, and therapeutic regimen understood.
6. Plan in place to meet ongoing needs.

**NURSING DIAGNOSIS:** **risk for Infection [progression/onset of opportunistic infection]****Possibly Evidenced By**

Chronic illness; inadequate vaccination [e.g., immunization against HCV, HCB, HPV]  
 Insufficient knowledge to avoid exposure  
 Alteration in skin integrity, traumatized tissue, stasis of body fluid  
 Immunosuppression; malnutrition  
 Invasive procedures

**Desired Outcomes/Evaluation Criteria—Client Will****Infection Severity NOC**

Be free of local and/or systemic signs of OIs.  
 Display usual orientation and mentation.  
 Achieve timely healing of any wounds or lesions.

**Risk Control NOC**

Identify individual risk factors.  
 Engage in behaviors/lifestyle changes to reduce risk of infection.

**ACTIONS/INTERVENTIONS****RATIONALE****Infection Control NIC****Independent**

Assess client knowledge and ability to maintain HIV treatment and opportunistic (OI) prophylactic regimen.

A multiple-medication regimen is difficult to maintain over a long period of time. Clients may adjust medication regimen based on side effects experienced, contributing to inadequate prophylaxis, active disease, and resistance. However, newer antiretroviral (ART or ARVT) regimens may increase adherence because they require less frequent dosing, fewer pills at each dose, and fewer side effects, thus maximizing quality of life and improving adherence to treatment. Note: Prophylaxis against an opportunistic infection (OI) is treatment given to HIV-infected individuals to prevent either a first episode of an OI (primary prophylaxis) or the recurrence of an OI (secondary prophylaxis). In the United States, prophylaxis is recommended to prevent three important OIs: *Pneumocystis jiroveci* pneumonia (PJP), *Mycobacterium avium* complex (MAC), and toxoplasmosis.

Provide a clean, well-ventilated environment. Screen visitors and staff for signs of infection and maintain isolation precautions for client protection, as indicated per protocol.

Reduces number of pathogens presented to the immune system and reduces possibility of client contracting a nosocomial infection.

Discuss extent and rationale for isolation precautions and maintenance of personal hygiene.

Promotes cooperation with regimen and may lessen feelings of isolation.

Monitor vital signs, including temperature.

Provides information for baseline and data to track changes. Recurrent temperature may indicate that the body is responding to a new infectious process or that medications are not effectively controlling noncurable infections.

(continues on page 806)

**ACTIONS/INTERVENTIONS (continued)**

Assess respiratory rate and depth; note dry spasmoid cough on deep inspiration, changes in characteristics of sputum, and presence of wheezes or rhonchi. Initiate respiratory isolation when etiology of productive cough is unknown.

Investigate reports of headache, stiff neck, and altered vision. Note changes in mentation and behavior. Monitor for nuchal rigidity or seizure activity.

Examine skin and oral mucous membranes for white patches or lesions. (Refer to NDs: impaired Skin Integrity; impaired oral Mucous Membrane Integrity.)

Clean client's nails frequently. File, rather than cut, and avoid trimming cuticles.

Monitor reports of heartburn, dysphagia, retrosternal pain on swallowing, increased abdominal cramping, and profuse diarrhea.

Inspect wounds and site of invasive devices, noting signs of local inflammation.

Use **Standard Precautions** when providing direct client care:

Perform hand hygiene before and after all care contacts, including before donning and after removing gloves. Instruct client and SO to wash hands, as indicated.

Use contact precautions where indicated.

Use other personal protective equipment (PPE) (e.g., gowns, masks, other eye and face protectors) where indicated.

Dispose of needles and sharps in rigid, puncture-resistant containers.

Label blood bags, body fluid containers, soiled dressings, or linens, and package appropriately for disposal per facility isolation protocol.

Clean up spills of body fluids or blood with bleach solution (1:10); add bleach to laundry.

**RATIONALE (continued)**

Respiratory congestion and distress may indicate developing respiratory disease, including PCP—the most common opportunistic disease in clients with CD4 count below 200. However, TB is on the rise and other fungal, viral, and bacterial infections may occur that compromise the respiratory system.

Neurological abnormalities are common and may be related to HIV or secondary infections. Symptoms may vary from subtle changes in mood or sensorium (personality changes or depression) to hallucinations, memory loss, severe dementias, seizures, and loss of vision. Central nervous system (CNS) infections (encephalitis is the most common) may be caused by protozoal and helminthic organisms or fungus.

Oral candidiasis, KS, herpes, CMV, and cryptococcosis are common opportunistic diseases affecting the cutaneous membranes.

Reduces risk of transmission of pathogens through breaks in skin. Note: Fungal infections along the nail plate are common.

Esophagitis may occur secondary to oral candidiasis, CMV, or herpes. Cryptosporidiosis is a parasitic infection responsible for watery diarrhea, often more than 15 L/d.

Early identification and treatment of secondary infection may prevent sepsis.

To reduce risk of transmission of HIV to healthcare providers and/or to reduce HIV-positive client's risk of exposure to potentially harmful disease-producing organisms.

The term *hand hygiene* includes both handwashing with either plain or antiseptic-containing soap and water and use of alcohol-based products (gels, rinses, foams) that do not require the use of water (Siegel et al, 2017).

Gloves are used to prevent contamination of healthcare personnel hands when anticipating direct contact with blood or body fluids, mucous membranes, nonintact skin (e.g., lesions, ulcerations), and other potentially infectious materials. OI symptoms requiring contact precautions may include (but are not limited to) body fluids visibly containing blood; presence of stool incontinence, draining wounds, uncontrolled secretions, pressure ulcers, presence of generalized rash, or presence of tubes and/or bags draining body fluids (Siegel et al, 2017; Waseem & Gernsheimer, 2017).

PPEs are required when there is potential contact with respiratory secretions and when healthcare procedures may generate splashes or sprays of blood, body fluids, secretions, and excretions (Siegel et al, 2017).

Prevents accidental inoculation of caregivers. Use of needle cutters and recapping is not to be practiced. Note: Accidental needlesticks should be reported immediately, with follow-up evaluations done per protocol.

Prevents cross-contamination and alerts appropriate personnel to exercise specific hazardous materials procedures.

Kills HIV and controls other microorganisms on surfaces.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<b>Collaborative</b> Administer antiretroviral medications, as indicated.	The goal of pharmacotherapy is to inhibit viral replication and to reduce morbidity and development of OIs.
****Refer to Care Plan the HIV-Positive Client, ND: deficient Knowledge, page 785 for medication examples.	
Administer preventive therapies as indicated (e.g., to prevent <i>Pneumocystis jiroveci</i> pneumonia (PJP; also called PCP), <i>Mycobacterium avium</i> complex (MAC), toxoplasmosis, tuberculosis,	All clients with HIV infection are susceptible to a wide range of opportunistic infections and are at higher risk to pathogenic organisms than the general population. Besides causing morbidity and mortality by themselves, OIs accelerate the progression of HIV disease itself. Prophylaxis against an opportunistic infection is treatment given to prevent either a first episode of an OI (primary prophylaxis) or the recurrence of an OI (secondary prophylaxis) (AIDS Education & Training Center [AETC], 2014; DHHS, 2017b).
Anti-infectives, such as trimethoprim-sulfamethoxazole (Bactrim), pentamidine (Pentacarinat), flucytosine (Ancobon), and clotrimazole (Femizole)	Early identification and treatment of secondary infection may prevent sepsis.
Refer to and encourage cooperation with local epidemiology agency or public health department.	This is a legal requirement. Accurate information facilitates tracking disease spread and groups affected.

NURSING DIAGNOSIS: <b>risk for deficient Fluid Volume</b>
<b>Possibly Evidenced By</b> Excessive fluid loss through normal routes (e.g., prolonged or copious diarrhea, profuse sweating, vomiting) Factors influencing fluid needs—hypermetabolic state, fever Insufficient fluid intake—nausea, anorexia, lethargy
<b>Desired Outcomes/Evaluation Criteria—Client Will</b>
<b>Hydration NOC</b> Maintain fluid volume at a functional level as evidenced by moist mucous membranes, good skin turgor, stable vital signs, and individually adequate urinary output.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Fluid/Electrolyte Management NIC</b> <i>Independent</i>	
Monitor vital signs, including central venous pressure (CVP) if available. Note hypotension, including postural changes.	Indicators of circulating fluid volume.
Note temperature elevation and duration of febrile episode. Administer tepid sponge baths, as indicated. Keep clothing and linens dry. Maintain comfortable environmental temperature.	Fever is one of the most frequent symptoms experienced by clients with HIV infection. Increased metabolic demands and associated excessive diaphoresis result in increased insensible fluid losses and dehydration.
Assess skin turgor, mucous membranes, and thirst.	Indirect indicators of fluid status.
Measure urinary output and specific gravity. Measure or estimate amount of diarrheal loss. Note insensible losses.	Increased specific gravity and decreasing urinary output reflects altered renal perfusion or circulating volume. Note: Monitoring fluid balance is difficult in the presence of excessive GI and insensible losses.
Weigh, as indicated.	Although weight loss may reflect muscle wasting, sudden fluctuations reflect state of hydration. Fluid losses associated with diarrhea can quickly create a crisis and become life-threatening.
Monitor oral intake and encourage fluids of at least 2500 mL/d, if not contraindicated.	Maintains fluid balance, reduces thirst, and keeps mucous membranes moist.

(continues on page 808)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Make fluids easily accessible to client. Encourage use of fluids that are tolerable to client and that replace needed electrolytes, such as Gatorade or broth.	Enhances intake. Certain fluids such as acidic fruit juices or iced beverages may be too painful to consume because of mouth lesions.
Eliminate foods potentiating diarrhea, such as spicy or high-fat foods, nuts, cabbage, and milk products. Provide lactose-free products, such as Resource or Advera. Adjust rate or concentration of enteral feedings, if indicated.	Diarrhea is a common problem for people with HIV, especially those with severely compromised immune system (due to gut-associated lymphoid tissue [GALT]) (Smith et al, 2000). Stress, antiretroviral medications, and problems digesting dairy products can also cause/exacerbate diarrhea.
<b>Collaborative</b> Administer fluids and electrolytes via feeding tube or intravenously (IV), as appropriate.	May be necessary to support or augment circulating volume, especially if oral intake is inadequate or nausea or vomiting persists. Minerals such as sodium, potassium, and calcium (lost from severe diarrhea) should be replenished.
Monitor laboratory studies, as indicated, for example:	
Serum and urine electrolytes	Alerts to possible electrolyte disturbances and determines replacement needs.
Blood urea nitrogen/creatinine (BUN/Cr)	Evaluates renal perfusion and function.
Stool specimen collection	Bowel flora changes can occur with multiple or single antibiotic therapy.
Administer medications, as indicated, for example:	
Antiemetics, such as prochlorperazine maleate (Compazine)	Reduces incidence of vomiting to reduce further loss of fluids and electrolytes.
Antidiarrheals, such as diphenoxylate (Lomotil), loperamide (Imodium), or paregoric, or antispasmodics, such as mepenzolate bromide (Cantil)	Decreases the amount and fluidity of stool; may reduce intestinal spasm and peristalsis. Note: Antibiotics may also be used to treat diarrhea if caused by infection.
Antipyretics, such as acetaminophen (Tylenol)	Helps reduce fever and hypermetabolic response, decreasing insensible losses. Note: Studies caution that Tylenol toxicity can occur more frequently in the client with AIDS, so it needs to be used with caution.
Maintain hypothermia blanket if used.	May be necessary when other measures fail to reduce excessive fever and insensible fluid losses.

### NURSING DIAGNOSIS: risk for ineffective Breathing Pattern

#### Possibly Evidenced By

Respiratory muscle fatigue—wasting of respiratory musculature  
 Fatigue  
 [Pneumonias; other pulmonary effects of HIV-related opportunistic infections]

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Respiratory Status NOC

Maintain effective respiratory pattern.  
 Experience no dyspnea or cyanosis, with breath sounds and chest x-ray clear or improving and arterial blood gases (ABGs) within client's normal range.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Respiratory Monitoring NIC</b> <i>Independent</i> Assess for presence and type of respiratory symptoms. Ask about previous pulmonary disorders and typical symptoms, as well as and recurrence/frequency of pneumonia as appropriate.	Some HIV-related OIs recur frequently, and knowledge of the client's past pulmonary history may suggest the etiology of the current illness. For example, bacterial pneumonias are common and frequently recurrent. Client with a history of PCP/PJP is at high risk of recurrence and must

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Auscultate breath sounds, noting areas of decreased or absent ventilation and presence of adventitious sounds—crackles, wheezes, and rhonchi.	be offered secondary PCP prophylaxis regardless of tCD4 cell count. PCP characteristically presents with fever, shortness of breath, and a dry, nonproductive cough. In contrast, pneumonia caused by <i>S. pneumoniae</i> or <i>H. influenzae</i> characteristically presents with fevers, shaking chills or rigors, shortness of breath, pleuritic chest pain, and a productive cough with purulent or blood-streaked sputum. Dyspnea may be mild or severe and present at rest. Fever, chills, night sweats, fatigue, anorexia, and weight loss also may be present. In addition, extrapulmonary symptoms (e.g., headache, stiff neck, abdominal tenderness or fullness) may be present and could aid in differentiating the various OIs and neoplasms (Huang, 2009).
Note rate and depth of respiration, use of accessory muscles, increased work of breathing, and presence of dyspnea, anxiety, and cyanosis.	Suggests developing pulmonary complications or infections, such as atelectasis or pneumonia. Note: PCP is often advanced before changes in breath sounds occur.
Assess changes in level of consciousness.	Tachypnea, cyanosis, restlessness, and increased work of breathing reflect respiratory distress and need for increased surveillance or medical intervention.
Investigate reports of chest pain.	Hypoxemia can result in changes ranging from anxiety and confusion to unresponsiveness.
<b>Ventilation Assistance NIC</b>	Pleuritic chest pain may reflect nonspecific pneumonitis or pleural effusions associated with malignancies.
Elevate head of bed. Have client turn, cough, and deep breathe as indicated.	Promotes optimal pulmonary function and reduces incidence of aspiration or infection due to atelectasis.
Suction airways as indicated, using sterile technique and observing safety precautions—mask, protective eyewear, if indicated.	Assists in clearing the ventilatory passages, thereby facilitating gas exchange and preventing respiratory complications.
Allow adequate rest periods between care activities. Maintain a quiet environment.	Reduces oxygen consumption.
<b>Collaborative</b>	
Monitor and graph serial ABGs or pulse oximetry.	Indicators of respiratory status and treatment needs and effectiveness.
Review serial chest x-rays.	Presence of diffuse infiltrates may suggest pneumonia, whereas areas of congestion or consolidation may reflect other pulmonary complications, such as atelectasis or KS lesions.
Assist with and instruct in use of incentive spirometer. Provide chest physiotherapy—percussion, vibration, and postural drainage.	Encourages proper breathing technique and improves lung expansion. Loosens secretions and dislodges mucous plugs to promote airway clearance. Note: In the event of multiple skin lesions, chest physiotherapy may be discontinued.
Provide humidified supplemental oxygen via appropriate means—cannula, mask, or intubation with mechanical ventilation.	Maintains effective ventilation and oxygenation to prevent or correct respiratory crisis.
Administer medications, as indicated, for example:	Choice of therapy depends on individual situation and infecting organism(s).
Bronchodilators, expectorants, and cough suppressants	May be needed to improve or maintain airway patency or help clear secretions.

(continues on page 810)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Antimicrobials, such as trimethoprim and sulfamethoxazole (TMP-SMX), or dapsone (Avlosulfon); atovaquone (Mepron); aerosolized pentamidine (not a complete listing)	The best way to prevent complications is by improving immune function with ongoing antiretroviral therapy (ART). While immune function is recovering, antibiotic prophylaxis should be given. Note: Many other antimicrobials are used to prevent or treat lung diseases associated with HIV infections (e.g., TB, bacterial pneumonias, MAC, KS, lung cancers, COPD, illicit drug or medication-induced diseases).
Prepare for and assist with procedures as indicated, such as bronchoscopy, lavage, and biopsy.	May be required to clear mucous plugs or obtain specimens for diagnosis.

NURSING DIAGNOSIS: risk for Bleeding
<b>Possibly Evidenced By</b>
Gastrointestinal condition (e.g., KS, MAC, cryptosporidiosis) Impaired liver function; inherent coagulopathy; malignancies Trauma; treatment regimen [e.g., surgery, medications] Insufficient knowledge of bleeding precautions
<b>Desired Outcomes/Evaluation Criteria—Client Will</b>
<b>Blood Loss Severity NOC</b>
Be free of active bleeding or excessive blood loss as evidenced by stable vital signs, usual mentation, and skin/mucous membranes free of pallor.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Bleeding Precautions NIC</b>	
<b>Independent</b>	
Avoid injections and rectal temperatures and rectal tubes; administer rectal suppositories with caution.	Protects client from procedure-related causes of bleeding; for example, insertion of thermometers or rectal tubes can damage or tear rectal mucosa. Note: Some medications may need to be given via suppository despite risk.
Maintain a safe environment—keep all necessary objects and call bell within client's reach and keep bed in low position.	Reduces accidental injury, which could result in bleeding.
Maintain bedrest or chair rest when platelets are low or as individually appropriate. Assess medication regimen.	Reduces possibility of injury, although activity needs to be maintained. May need to discontinue or reduce dosage of a drug. Note: Client can have a surprisingly low platelet count without bleeding.
Hematest body fluids—urine, stool, and vomitus—for occult blood.	Prompt detection of bleeding and initiation of therapy may prevent critical loss of blood. Note: Clinical studies have revealed that rectal bleeding is present in 45% of patients with HIV-related squamous cell carcinoma of anus (SCCA) (Department of Veterans Affairs [VA], 2009).
Observe for and report epistaxis, hemoptysis, hematuria, nonmenstrual vaginal bleeding, or oozing from lesions, body orifices, or IV insertion sites.	Spontaneous bleeding may indicate presence of active HIV-related condition (e.g., TB) or development of disseminated intravascular coagulation (DIC) or immune thrombocytopenia, necessitating further evaluation and prompt intervention.
Monitor for changes in vital signs and skin color, such as BP, pulse, respirations, and skin pallor or discoloration.	Presence of bleeding or hemorrhage may lead to circulatory failure and shock.
Evaluate change in level of consciousness.	May reflect cerebral bleeding or diminished cerebral blood flow and oxygenation.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<b>Collaborative</b>	
Review laboratory studies, such as prothrombin time (PT), international normalized ratio (INR), activated partial thromboplastin time (aPTT), clotting time, platelets, and Hgb and Hct.	Detects alterations in clotting capability; identifies therapy needs. Note: Many individuals display platelet counts below 50,000 and may be asymptomatic, necessitating regular monitoring.
Administer blood products, as indicated.	Transfusions may be required in the event of persistent or massive spontaneous bleeding.
Avoid use of aspirin products and NSAIDs, especially in presence of gastric lesions.	These medications reduce platelet aggregation, prolonging the coagulation process, and may cause further gastric irritation, increasing risk of bleeding. Note: Aspirin is contraindicated even in the short term because of its nonreversible effect on platelets.

### NURSING DIAGNOSIS: imbalanced Nutrition: less than body requirements

#### May Be Related To

Insufficient dietary intake—anorexia, nausea, vomiting, hyperactive gag reflex, fatigue  
Inability to absorb nutrients—intestinal disturbances, GI tract (HIV-related) infections; (HIV medications)

#### Possibly Evidenced By

Body weight 20% or more below ideal weight range [decreased subcutaneous fat or muscle mass]  
Food intake less than recommended daily allowances (RDA); insufficient interest in food; food aversion; alteration in taste sensation; sore buccal cavity  
Abdominal cramping [nausea, vomiting]  
[Abnormal laboratory results—vitamin, mineral, and protein deficiencies, electrolyte imbalances]

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Nutritional Status NOC

Maintain weight or display weight gain toward desired goal.  
Report improved energy level.

##### Nutritional Status: Biochemical Measures NOC

Be free of signs of malnutrition, with lab values (e.g., albumin/prealbumin, hemoglobin) stable or improving.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Nutritional Monitoring NIC</b>	
<b>Independent</b>	
Assess ability to chew, taste, and swallow.	Lesions of the mouth, throat, and esophagus are often caused by candidiasis, herpes simplex, hairy leukoplakia, or KS and other cancers, and metallic or other taste changes caused by medications may cause dysphagia, limiting client's ability to ingest food and reducing desire to eat.
Auscultate bowel sounds.	Hypermotility of intestinal tract is common and is associated with vomiting and diarrhea, which may affect choice of diet or route. Note: Lactose intolerance and malabsorption, such as associated with CMV, MAC, or cryptosporidiosis, contribute to diarrhea and may necessitate change in diet or supplemental formula, such as Advera or Resource.
Weigh, as indicated. Evaluate weight in terms of weight before onset of illness. Compare serial weights and anthropometric measurements.	Indicator of nutritional needs and adequacy of intake.
Note drug side effects. Schedule medications between meals if possible.	Prophylactic and therapeutic medications can have side effects affecting nutrition, for example, altered taste, anorexia, nausea, and vomiting.

(continues on page 812)

**ACTIONS/INTERVENTIONS (continued)****RATIONALE (continued)****Nutritional Therapy NIC**

Plan diet with client and SO, incorporating foods client likes or food from home. Encourage small, frequent meals and snacks of nutritionally dense foods and nonacidic foods and beverages, with choice of foods palatable to client. Encourage high-calorie, nutritious foods, some of which may be considered appetite stimulants. Note time of day when appetite is best, and try to serve a larger meal at that time.

Limit food(s) that induce nausea or vomiting or are poorly tolerated by client with mouth sores or dysphagia. Avoid serving very hot liquids and foods.

Serve foods that are easy to swallow, such as eggs, ice cream, or cooked vegetables.

Limit fluid intake with meals unless fluid has nutritional value.

Encourage as much physical activity as possible.

Provide frequent mouth care, observing secretion precautions. Avoid alcohol-containing mouthwashes.

Provide rest period before meals. Avoid stressful procedures close to mealtime.

Remove existing noxious environmental stimuli or conditions that aggravate gag reflex.

Encourage client to sit up for meals.

Record ongoing caloric intake.

**Collaborative**

Review laboratory studies, such as BUN, glucose, liver function studies, electrolytes, protein, and albumin or prealbumin.

Maintain nothing by mouth (NPO) status when appropriate.

Insert and maintain nasogastric (NG) tube, as indicated.

Consult with dietitian or nutritional support team.

Administer enteral or parenteral feedings, as indicated.

Administer medications, as indicated, for example:

Antiemetics, such as prochlorperazine (Compazine), ondansetron (Zophran); cannabidiol (CBD) vapors; dronabinol (Marinol)

Including client in planning gives a sense of control of environment and may enhance intake. Fulfilling cravings for desired food may also improve intake. Note: In this population, foods with a higher fat content may be recommended (if tolerated) to enhance taste and oral intake.

Pain in the mouth or fear of irritating oral lesions may cause client to be reluctant to eat.

These measures may be helpful in increasing food intake.

Gastric fullness diminishes appetite and food intake.

May improve appetite and general feelings of well-being.

Reduces discomfort associated with nausea or vomiting, oral lesions, mucosal dryness, and halitosis. A clean mouth may enhance appetite.

Minimizes fatigue; increases energy available for work of eating.

Reduces stimulus of the vomiting center in the medulla.

Facilitates swallowing and reduces risk of aspiration.

Identifies need for supplements or alternative feeding methods.

Indicates nutritional status and organ function and identifies replacement needs. Note: Nutritional tests can be altered because of disease processes and response to some medications or therapies.

May be needed to reduce nausea or vomiting.

May be required to reduce vomiting or to administer tube feedings. Note: Esophageal irritation from existing infection, such as *Candida*, herpes, or KS, may provide site for secondary infections or trauma; therefore, NG tube should be used with caution.

Provides for diet based on nutritional needs and appropriate route.

Enteral feedings are preferred because they cost less and carry less risk of exacerbating endocrine dysfunction than total parenteral nutrition (TPN). However, TPN may be required when oral or enteral feedings are not tolerated. TPN is reserved for those whose gut cannot absorb even an elemental formula, such as Vivonex, or those with severe refractory diarrhea.

Reduces incidence of nausea and vomiting, possibly enhancing oral intake. Note: Medical marijuana is widely recognized as an effective treatment for symptoms of HIV/AIDS as well as the side effects related to the antiretroviral therapies that constitute the first line of treatment for HIV/AIDS. According to the Institute of Medicine (IOM, 1999), "For patients such as those with

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Gastric protective agents such as sucralfate (Carafate) suspension; oral suspension sometimes known as Magic Mouthwash, which is a mixture of Maalox, diphenhydramine (Benadryl), and lidocaine (Xylocaine)	AIDS or who are undergoing chemotherapy and who suffer simultaneously from severe pain, nausea, and appetite loss, cannabinoid drugs might offer broad-spectrum relief not found in any other single medication.” The IOM report did find more potential promise in synthetic cannabinoid drugs than in smoked marijuana (IOM, 1999). The ACP encourages the use of nonsmoked forms of THC that have proven therapeutic value (American College of Physicians [ACP], 2008). The IOM follow-up reported on the benefits of utilizing vaporizers as a safer delivery system, eliminating harmful effects of smoking (IOM, 2009).
Vitamin supplements, as prescribed by physician and/or nutritionist	Given with meals—swish and hold in mouth—to relieve mouth pain and enhance intake. Mixture may be swallowed in presence of pharyngeal or esophageal lesions.
Appetite stimulants, such as dronabinol (Marinol), megestrol (Megace), or oxandrolone (Oxandrin)	Corrects vitamin deficiencies resulting from decreased food intake and/or disorders of digestion and absorption in the GI system. Note: Many supplements (vitamins, minerals, protein powder, meal replacement drinks, amino acids, herbs) are not regulated by the FDA and could contain ingredients that interfere with ART medications.
Antidiarrheals, such as diphenoxylate (Lomotil), loperamide (Imodium), or octreotide (Sandostatin)	Marinol, an antiemetic, and Megace, an antineoplastic, act as appetite stimulants in the presence of AIDS.
Antifungals, such as ketoconazole (Nizoral) or fluconazole (Diflucan)	These drugs inhibit GI motility, subsequently decreasing diarrhea. Imodium or Sandostatin is an effective treatment for secretory diarrhea with secretion of water and electrolytes by intestinal epithelium.
	These may be given to treat or prevent infections involving the GI tract.

### NURSING DIAGNOSIS: acute/chronic Pain

#### May Be Related To

Biological injury agent (e.g., HIV and HIV-related infections; neoplasms; malignancies)

Physical injury agent (e.g., tissue inflammation or destruction—internal/external cutaneous lesions, rectal excoriation; HIV-related peripheral neuropathies; necrosis)

Fatigue; malnutrition; emotional distress

#### Possibly Evidenced By

Self-reports of pain intensity/characteristics using standardized pain scale/instrument

Self-focusing, narrowed focus; reduced interaction with people

Guarding and protective behaviors; emotional distress

Alteration in appetite, sleep pattern, in ability to continue previous activities

Changes in vital signs (acute)

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Pain Level NOC

Verbalize and demonstrate relief or control of pain/discomfort.

Demonstrate relaxed posture and facial expression.

Be able to sleep or rest appropriately.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Pain Management NIC</b>	
<i>Independent</i>	
Assess pain reports, noting location, intensity (0-10 or similar coded scale), frequency, and time of onset. Note nonverbal cues, such as restlessness, tachycardia, or grimacing.	Indicates need for, and effectiveness of, interventions and may signal development or resolution of complications. Note: Chronic pain does not produce autonomic changes; however, acute and chronic pain can coexist.
Encourage client to report pain as it develops rather than waiting until level is severe.	Efficacy of comfort measures and medications is improved with timely intervention.
Encourage verbalization of feelings.	Can reduce anxiety and fear and thereby reduce perception of intensity of pain.
Provide diversional activities, such as reading, visiting, music, television, video games.	Refocuses attention; may enhance coping abilities.
Perform palliative measures—repositioning, massage, or ROM exercises of affected joints.	Promotes relaxation and decreases muscle tension.
Instruct client in, and encourage use of, visualization, guided imagery, progressive relaxation, deep-breathing techniques, meditation, and mindfulness.	Promotes relaxation and feeling of well-being. May decrease the need for opioid analgesics (CNS depressants) when a neurological or motor degenerative process is already involved. May not be successful in presence of dementia, even when dementia is minor. Note: Mindfulness is the skill of staying in the here and now.
Provide oral care. (Refer to ND: impaired oral Mucous Membrane Integrity.)	Oral ulcerations or lesions may cause severe discomfort.
<i>Collaborative</i>	
Administer analgesics, antipyretics, or opioid analgesics. Use patient-controlled analgesia (PCA) or provide around-the-clock analgesia with rescue doses, as needed.	Provides relief of pain and discomfort; reduces fever. PCA or around-the-clock medication keeps the blood level of analgesia stable, preventing cyclic undermedication or overmedication.

### NURSING DIAGNOSIS: risk for impaired Skin Integrity

#### Possibly Evidenced By

Immunodeficiency  
Inadequate nutrition  
Alteration in fluid volume, skin turgor; humidity; moisture; excretions; secretions  
Pressure over bony prominence(s); impaired circulation; alteration in sensation

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Risk Control NOC

Demonstrate behaviors or techniques to prevent skin breakdown and promote healing.

#### Wound Healing: Secondary Intention NOC

Be free of or display improvement in wound or lesion healing.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Skin Surveillance NIC</b>	
<i>Independent</i>	
Assess skin daily. Note color, turgor, circulation, and sensation. Describe and measure lesions and observe changes.	Establishes comparative baseline providing opportunity for timely intervention.
Provide and instruct in good skin hygiene—wash thoroughly, pat dry carefully, and apply moisturizing lotion or appropriate cream.	Maintaining clean, dry skin provides a barrier to infection. Patting skin dry instead of rubbing reduces risk of dermal trauma to dry, fragile skin. Note: Isolation precautions are required when extensive or open cutaneous lesions are present.
Reposition frequently. Use turn sheet as needed. Encourage periodic weight shifts. Protect bony prominences with pillows, heel and elbow pads, or sheepskin.	Reduces stress on pressure points, improves blood flow to tissues, and promotes healing.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Maintain clean, dry, wrinkle-free linen, preferably soft cotton fabric.	Skin friction caused by movement over wet, wrinkled, or rough sheets leads to irritation of fragile skin and increases risk of infection.
Encourage ambulation as tolerated.	Decreases pressure on skin from prolonged bedrest.
Cleanse perianal area by removing stool with water and mineral oil or commercial product. Avoid use of toilet paper if vesicles are present. Apply protective creams (e.g., zinc oxide, A & D ointment).	Prevents maceration caused by diarrhea and keeps perianal lesions dry. Note: Use of toilet paper may abrade lesions.
File nails regularly.	Long or rough nails increase risk of dermal damage.

**Wound Care NIC**

Cover open pressure ulcers with sterile dressings or protective barrier, such as Tegaderm or DuoDerm, as indicated.

**Collaborative**

Provide foam, flotation, or alternate pressure mattress or bed.

If open skin lesions develop, obtain cultures and notify physician for treatment interventions.

May reduce bacterial contamination and promote healing.

Reduces pressure on skin and tissues, decreasing tissue ischemia.

Certain OIs can impact the skin (e.g., bacterial infections causing painful skin bumps or abscesses, or viral infections resulting in warts, sores, shingles). Cultures may be necessary to reveal pathogens and suggest appropriate treatment choices.

Refer to physical therapy for regular exercise program.

Promotes improved muscle tone and skin health.

**NURSING DIAGNOSIS: impaired oral Mucous Membrane Integrity****May Be Related To**

Immunodeficiency; stressors

Dehydration; malnutrition

Inadequate oral hygiene

Treatment regimen (e.g., side effects pharmaceutical agents); chemotherapy

**Possibly Evidenced By**

Open lesions/ulcers; oral vesicles

Oral pain/discomfort

Stomatitis; white patches in mouth; gingivitis

Difficulty eating; impaired ability to swallow

**Desired Outcomes/Evaluation Criteria—Client Will****Oral Hygiene NOC**

Display intact mucous membranes, which are pink, moist, and free of inflammation or ulcerations.

**Risk Control NOC**

Demonstrate techniques to restore or maintain integrity of oral mucosa.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Oral Health Restoration NIC</b>	

**Independent**

Assess mucous membranes and document all oral lesions. Note reports of pain, swelling, and difficulty with chewing or swallowing.

Edema, open lesions, and crusting on oral mucous membranes and throat may cause pain and difficulty with chewing or swallowing. Note: More than 90% of persons infected with HIV who are not receiving highly active antiretroviral therapy (HAART) eventually develop oropharyngeal candidiasis (OPC), and 10% eventually develop at least one episode of esophageal candidiasis (Hidalgo & Vasquez, 2017).

(continues on page 816)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Provide oral care daily and after food intake, using soft toothbrush, nonabrasive toothpaste, nonalcoholic mouthwash, floss, and lip moisturizer.	Alleviates discomfort, prevents acid formation associated with retained food particles, and promotes feeling of well-being.
Rinse oral mucosal lesions with saline or dilute hydrogen peroxide or baking soda solutions.	Reduces spread of lesions and encrustations from candidiasis and promotes comfort.
Suggest use of sugarless gum or candy or commercial salivary substitute.	Stimulates flow of saliva to neutralize acids and protect mucous membranes. Note: Sorbitol in some artificially sweetened products can increase risk for loose stools.
Plan diet to avoid salty, spicy, abrasive, and acidic foods or beverages. Check for temperature tolerance of foods. Offer cool or cold smooth foods.	Abrasive foods may open healing lesions. Open lesions are painful and aggravated by salt, spices, and acidic foods and beverages. Extreme cold or heat can cause pain to sensitive mucous membranes.
Encourage oral intake of at least 2500 mL/d.	Maintains hydration; prevents drying of oral mucous membranes.
Encourage client to refrain from smoking.	Smoke is drying and irritating to mucous membranes.
<b>Collaborative</b>	
Obtain culture specimens of lesions.	Reveals causative agents and identifies appropriate therapies.
Administer medications, as indicated, such as topical antifungal agents (e.g., nystatin (Mycostatin), clotrimazole (Mycelex), amphotericin B oral suspension), or systemic azoles—fluconazole (Diflucan), itraconazole (Onmel, Sporanix) (Hidalgo & Vasquez, 2017).	Specific drug choice depends on particular type and location of <i>Candida</i> infection.
Apply Magic Mouthwash (mixture of Maalox, diphenhydramine [Benadryl], and lidocaine [Xylocaine]), or similar product to oral lesions, as prescribed.	Reduces local pain of <i>Candida</i> and other oral lesions.
Refer for dental consultation, if appropriate.	May require additional therapy to prevent dental losses.

## NURSING DIAGNOSIS: Fatigue

### May Be Related To

Illness; physical deconditioning  
Stressors; anxiety; depression  
Malnutrition

### Possibly Evidenced By

Insufficient energy; tiredness; lethargy; increase in rest requirements; nonrestorative sleep pattern; increase in physical symptoms  
Disinterest in surroundings; introspection; alteration in concentration  
Impaired ability to maintain usual routines/physical activity; guilt about difficulty maintaining responsibilities

### Desired Outcomes/Evaluation Criteria—Client Will

#### Fatigue Level NOC

Report improved sense of energy.  
Participate in desired activities at level of ability.  
Participate in recommended treatment program.

#### Energy Conservation NOC

Identify individual areas of control and engage in energy conservation techniques.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Energy Management NIC</b> <i>Independent</i>	
Obtain client/SO descriptions and rating (using numerical scale) of fatigue. Note presence of additional concerns (e.g., irritability, lack of concentration, relationship difficulties).	Helps to evaluate impact of fatigue on client's quality of life and identify areas that are exacerbating low energy. Note: A recent study reported that fatigue affects nearly 90% of people living with HIV and has been reported as one of the most persistent and troubling symptoms they experience. An elevated risk of fatigue may be related to hematologic and metabolic changes (direct results of HIV infection and treatment), as well as psychological and psychosocial stressors (Barroso et al, 2015).
Assess sleep patterns and other factors that may be aggravating fatigue.	Multiple factors can cause and aggravate fatigue, including sleep deprivation, emotional distress associated with diagnosis, side effects of drugs, or developing HIV-related complications.
Encourage evaluation of fatigue when antiretroviral treatment is initiated or medications have been added to regimen.	Fatigue is present in variable degrees as part of HIV infection process but is often aggravated by nutritional deficiencies and side effects of certain medications. Even though anti-HIV drugs may improve energy levels, some may also cause fatigue. Tiredness, fatigue, insomnia, and sleep disturbances are possible side effects of several anti-HIV drugs. Side effects are most common in the first few weeks after starting HIV treatment, or when PIs are added or changed, fatigue may worsen.
Discuss reality of client's feelings of exhaustion and identify limitations imposed by fatigue state. Advise client to maintain a fatigue diary, and note daily energy patterns—peaks and valleys.	Helpful in planning activities within tolerance levels. Clients often expect too much of themselves, believing that they should be able to do more.
Assist client to set realistic activity goals, determining individual priorities and responsibilities.	Client may need to alter priorities and delegate some responsibilities to manage fatigue and optimize performance.
Discuss energy conservation techniques, such as sitting instead of standing for activities, as appropriate.	Enables client to become aware of ways in which energy expenditure can be maximized to complete necessary tasks.
Review importance of meeting individual nutritional needs.	Adequate nutrition is needed for optimizing energy production. (Refer to ND: imbalanced Nutrition: less than body requirements, following.)
Encourage adequate rest periods during the day, routine schedule for bedtime and arising, and scheduling activities during time of best energy.	Helps client recoup energy to manage desired activities.
Instruct in stress management techniques, such as breathing exercises, visualization, and music and light therapy.	Reduction of stress factors in client's life can minimize energy output.
Identify available resources and support systems.	May require outside assistance with many things, including homemaking and maintenance activities and child care.

### NURSING DIAGNOSIS: risk for acute/chronic Confusion

#### Possibly Evidenced By

Infection [HIV-associated dementia]  
Dehydration; malnutrition; impaired metabolic functioning [electrolyte imbalance, increased blood urea nitrogen (BUN)/creatinine]  
Pharmaceutical agents—multiple medications

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Cognition NOC

Maintain usual reality orientation and optimal cognitive functioning.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Cognitive Stimulation NIC</b>	
<b>Independent</b>	
Assess mental and neurological status using appropriate tools.	Establishes functional level at time of admission and provides baseline for future comparison.
Consider effects of emotional distress, such as anxiety, grief, and anger.	May contribute to reduced alertness, confusion, withdrawal, and hypoactivity, requiring further evaluation and intervention.
Monitor medication regimen and usage.	Actions and interactions of various medications, prolonged drug half-life, and altered excretion rates result in cumulative effects, potentiating risk of toxic reactions. Some drugs may have adverse side effects, such as haloperidol (Haldol), which can seriously impair motor function in clients with AIDS dementia complex.
Investigate changes in behavior, response to stimuli, orientation, and level of consciousness or development of headache, nuchal rigidity, vomiting, fever, loss of balance, or seizure activity.	Changes may occur for numerous reasons, including development or exacerbation of opportunistic diseases or CNS infection. Note: Early detection and treatment of CNS infection may limit permanent impairment of cognition.
Maintain a pleasant environment with appropriate auditory, visual, and cognitive stimuli.	Providing normal environmental stimuli can help in maintaining some sense of reality orientation.
Provide cues for reorientation such as radio, television, calendars, clocks, or a room with an outside view. Use client's name; identify yourself. Maintain consistent personnel and structured schedules, as appropriate.	Frequent reorientation to place and time may be necessary, especially during fever or acute CNS involvement. Sense of continuity may reduce associated anxiety.
Discuss use of datebooks, lists, and other devices to keep track of activities.	These techniques help client manage problems of forgetfulness.
Encourage family/SO to socialize and provide reorientation with current news and family events.	Familiar contacts are often helpful in maintaining reality orientation, especially if client is hallucinating.
Encourage client to do as much as possible, such as dressing and grooming and visiting with friends.	Can help maintain mental abilities for longer period.
Provide support for SO. Encourage discussion of concerns and fears.	Bizarre behavior or deterioration of abilities may be very frightening for SO and makes management of care and dealing with situation difficult. SO may feel a loss of control as stress, anxiety, burnout, and anticipatory grieving impair coping abilities.
Provide information about care on an ongoing basis. Answer questions simply and honestly. Repeat explanations as needed.	Can reduce anxiety and fear of unknown; can enhance client's understanding, involvement, and cooperation in treatment when possible.
<b>Cognitive Restructuring NIC</b>	
Reduce provocative or noxious stimuli. Maintain bedrest in quiet, darkened room, if indicated.	If client is prone to agitation, violent behavior, or seizures, reducing external stimuli may be helpful.
Decrease noise, especially at night.	Promotes sleep, reducing cognitive symptoms and effects of sleep deprivation.
Set limits on maladaptive or abusive behavior; avoid open-ended choices.	Provides sense of security and stability in an otherwise confusing situation.
Maintain safe environment, such as excess furniture out of the way, call bell within client's reach, bed in low position, rails up; restriction of smoking unless monitored by caregiver and SO; seizure precautions; and soft restraints, if indicated.	Decreases the possibility of client injury.
Discuss future expectations and treatment if dementia is diagnosed. Use concrete terms.	Obtaining information that some medications have been shown to improve cognition can provide hope.
<b>Collaborative</b>	
Assist with diagnostic studies, such as mental status exams, MRI, CT scan, and spinal tap, and monitor laboratory studies (BUN/Cr, electrolytes, ABGs), as indicated.	Choice of tests or studies depends on clinical manifestations and index of suspicion, because changes in mental status may reflect a wide variety of causative factors, such as CMV meningitis or encephalitis, drug toxicity, electrolyte imbalances, and altered organ function.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Administer medications, as indicated, for example: Retrovir (AZT), nevirapine (Viramune), amprenavir (Agenerase), amphotericin B (Fungizone), and other medications alone or in combination	HIV medications that are known to cross the blood-brain barrier and may help slow or stop HIV damage to the brain. Note: Antifungals have been useful in treatment of cryptococcosis meningitis (POZ,n.d.)
Antipsychotics, such as haloperidol (Haldol), antidepressants such as fluoxetine (Prozac) and bupropion (Wellbutrin), and/or antianxiety agents, such as lorazepam (Ativan)	Shown to improve neurological and mental functioning for undetermined period of time. Cautious use may help with problems of sleeplessness, emotional lability, hallucinations, suspiciousness, and agitation (POZ, n.d.).
Provide controlled environment and behavioral management, as indicated.	Team approach may be required to protect client when mental impairment, especially delusions, threatens client safety.
Refer to counseling, as indicated.	May help client gain control in presence of thought disturbances or psychotic symptoms.

### NURSING DIAGNOSIS: Death Anxiety

#### May Be Related To

Uncertainty of prognosis; perceived imminence of death  
Anticipation of pain, suffering  
Uncertainty about life after death, encountering a higher power  
Anticipation of impact of death on others

#### Possibly Evidenced By

Negative thoughts related to death and dying; deep sadness; powerlessness  
Fear of pain or suffering related to dying, or prolonged dying process

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Dignified Life Closure NOC

Verbalize acceptance of reality of situation.  
Express hopefulness and sense of control.  
Appear calm and peaceful.  
Participate in decisions about care and death.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Dying Care NIC</b>	
<i>Independent</i>	
Assure client of confidentiality within limits of situation.	Provides reassurance and opportunity for client to problem-solve solutions to anticipated situations.
Maintain frequent contact with client. Talk with and touch client. Limit use of isolation clothing and masks.	Provides assurance that client is not alone or rejected; conveys respect for and acceptance of the person, fostering trust.
Provide accurate, consistent information regarding prognosis. Avoid arguing about client's perceptions of the situation.	Can reduce anxiety and enable client to make decisions or choices based on realities.
Be alert to signs of denial or depression, including withdrawal or angry, inappropriate remarks. Determine presence of suicidal ideation and assess potential on a scale of 1 to 10.	Client may use defense mechanism of denial and continue to hope that diagnosis is inaccurate. Feelings of guilt and spiritual distress may cause client to become withdrawn and believe that suicide is a viable alternative. Although client may be too "sick" to have enough energy to implement thoughts, ideation must be taken seriously and appropriate intervention initiated.
Provide open environment in which client feels safe to discuss feelings or to refrain from talking.	Helps client feel accepted in present condition without feeling judged and promotes sense of dignity and control.

(continues on page 820)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Permit expressions of anger, fear, and despair without confrontation. Give information that feelings are normal and are to be appropriately expressed.	Acceptance of feelings allows client to begin to deal with situation.
Recognize and support the stage client and family are at in the grieving process. (Refer to CP: Cancer, ND: Grieving.)	Choice of interventions is dictated by stage of grief and coping behaviors, such as anger, withdrawal, and denial.
Explain procedures, providing opportunity for questions and honest answers. Arrange for someone to stay with client during anxiety-producing procedures and consultations.	Accurate information allows client to deal more effectively with the reality of the situation, thereby reducing anxiety and fear of the unknown.
Identify and encourage client interaction with support systems. Encourage verbalization and interaction with family and SO.	Reduces feelings of isolation. If family support systems are not available, outside sources such as local AIDS task force may be needed.
Provide reliable and consistent information and support for SO.	Allows for better interpersonal interaction and reduction of anxiety and fear.
Include SO as indicated when major decisions are to be made.	Ensures a support system for client and allows SO the chance to participate in client's life. Note: If client, family, and SO are in conflict, separate care consultations and visiting times may be needed.
Encourage advance directives or living will and durable medical power of attorney documents, with specific and precise instructions regarding acceptable and unacceptable procedures to prolong life and explaining the various options clearly.	Many factors associated with the treatments used in this debilitating and often fatal disease process place client at the mercy of medical personnel and other unknown people who may be making decisions for and about client without regard for client's wishes, increasing loss of independence. Note: Many individuals do not understand medical terminology or options such as percutaneous endoscopic gastrostomy (PEG) tube for short- or long-term feeding and pain management techniques.
Discuss desires and assist with planning for funeral, as appropriate.	The individual can gain a sense of completion and value to his or her life when he or she decides to be involved in planning this final ceremony. This provides an opportunity to include things that are of importance to the client.
Refer to CP Palliative and Hospice/End-of-Life Care, ND Grieving/Death Anxiety.	Provides additional interventions to support client/SO needs.
<b>Collaborative</b> Refer to counseling—psychiatric clinical nurse specialist, psychiatrist, or social worker.	May require further assistance in dealing with diagnosis/prognosis, especially when suicidal thoughts are present.
Provide contact with other resources, as indicated:	
Spiritual advisor	Provides opportunity for addressing spiritual concerns.
Hospice staff	May help relieve anxiety regarding end-of-life care and provide physical and emotional support for client and SO.

## NURSING DIAGNOSIS: Social Isolation

### May Be Related To

Social behavior incongruent with norms  
Alteration in wellness, physical appearance, mental status  
Insufficient personal resources

### Possibly Evidenced By

Illness; disabling condition  
Aloneness imposed by others; history of rejection  
Absence of support system; values incongruent with cultural norms

### Desired Outcomes/Evaluation Criteria—Client Will

#### Loneliness Severity NOC

Express sense of satisfaction with relationship(s).  
Reports sense of acceptance or belonging.

**NURSING DIAGNOSIS:** **Social Isolation** (continued)**Social Support NOC**

Identify supportive individual(s).  
Develop stable support system.  
Use resources for assistance, as appropriate.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Support System Enhancement NIC</b>	
<i>Independent</i>	
Ascertain client's perception of situation.	Isolation may be partly self-imposed because client fears rejection or reaction of others.
Spend time talking with client during and between care activities. Be supportive, allowing for verbalization. Treat with dignity and regard for client's feelings.	Client may experience physical isolation as a result of current medical status and some degree of social isolation secondary to diagnosis of AIDS.
Identify factors that can lead to feelings of powerlessness (e.g., diagnosis of a terminal illness, lack of support systems, rejection by others, and lack of knowledge about present situation).	Powerlessness is most prevalent in a client newly diagnosed with HIV and when dying of AIDS. Fear of AIDS (by the general population and the client's family/SO) is the most profound cause of client's isolation. Multiple medications and inconvenient dosing regimens can also reduce a person's sense of control, independence, and general quality of life.
Limit or avoid use of mask, gown, and gloves when possible, such as when talking to client.	Reduces client's sense of physical isolation and provides positive social contact, which may enhance self-esteem and decrease negative behaviors.
Identify support systems available to client, including presence of, relationship with, immediate and extended family.	When client has assistance from SO, feelings of loneliness and rejection are diminished. However, for some homosexual clients, this may be the first time that the family has been made aware that client lives an alternative lifestyle. Note: Client may not receive needed support for coping with life-threatening illness and associated grief because of discrimination, fear, and lack of understanding—AIDS hysteria.
Explain isolation precautions and procedures to client and SOs.	Gloves, gowns, and mask are not routinely required with a diagnosis of AIDS, except when contact with secretions or excretions is expected. Misuse of these barriers enhances feelings of emotional and physical isolation. When precautions are necessary, explanations help client understand reasons for procedure and provide feeling of inclusion in what is happening.
Encourage open visitation, as appropriate, telephone contacts, and social activities within level of tolerance.	Participation with others can foster a feeling of belonging.
Encourage active role of contact with SO.	Helps reestablish a feeling of participation in a social relationship. May lessen likelihood of suicide attempts.
Be aware of client's/SO's view of self-regarding HIV diagnosis and concerns or reports of problems associated with diagnosis (e.g., negative attitudes expressed in various ways; lack of access to healthcare or services; loss of relationships, homelessness, etc.).	Research reveals that stigma continues to be experienced by persons living with HIV/AIDS (Johnson, 2015). Literature indicates that higher levels of stigma correlate with inability or reluctance to seek medical attention, a decrease in compliance with antiretroviral therapy, and an increase in psychological distress such as anxiety, depression, hopelessness, and risk for AIDS-related conditions. These issues are especially prevalent in certain populations (e.g., homeless, the LGBTQ community, persistent poverty) (Gerber, 2013; Varni et al, 2012).
Develop a plan of action with client that looks at available resources and supports healthy behaviors. Help client problem-solve solution to short-term or imposed isolation.	Having a plan promotes a sense of control over own life and gives client something to look forward to and actions to accomplish.

(continues on page 822)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Be alert to verbal and nonverbal cues, including withdrawal, statements of despair, helplessness, and sense of aloneness. Ask client if thoughts of suicide are being entertained.	Indicators of despair and suicidal ideation are often present. When these cues are acknowledged by the caregiver, client is usually willing to talk about thoughts of suicide and sense of isolation and hopelessness.
<b>Collaborative</b> Refer to resources, such as social services counselors and local and national AIDS organizations.	Establishes support systems; may reduce feelings of isolation.
Provide for placement in sheltered community when necessary.	May need more specific care when unable to be maintained at home or when SO cannot manage care.

## NURSING DIAGNOSIS: **ineffective Health Management**

### May Be Related To

Difficulty navigating complex healthcare system, managing complex treatment regimen; insufficient knowledge of therapeutic regimen  
 Decisional conflict; family conflict; family pattern of healthcare  
 Economically disadvantaged; powerlessness; perceived seriousness of condition, susceptibility, benefit or barrier  
 Insufficient social support

### Possibly Evidenced By

Difficulty with prescribed regimen  
 Failure to include treatment regimen in daily living  
 [Unexpected acceleration of illness symptoms]

### Desired Outcomes/Evaluation Criteria—Client Will

#### Self-Management: Chronic Disease **NOC**

Verbalize understanding of condition, disease process, and potential complications.  
 Identify relationship of current signs and symptoms to the disease process and correlate symptoms with causative factors.  
 Demonstrate behaviors necessary therapeutic regimen.  
 Identify and use available resources.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Teaching: Disease Process <b>NIC</b></b>	
<b>Independent</b>	
Review disease process and future expectations.	Provides knowledge base from which client can make informed choices. Note: Clients with AIDS are usually aware of current prognosis unless newly diagnosed.
Determine level of dependence and physical condition. Note extent of care and support available from family and SO and need for supplemental caregivers.	Helps plan amount of care and symptom management required and need for additional resources.
Instruct client and caregivers concerning infection control:	Reduces risk of transmission of HIV and opportunistic infections.
Using good handwashing techniques for everyone, including client, family, and caregivers	
Using gloves when handling bedpans, dressings, and soiled linens	
Wearing mask if client has productive cough	
Placing soiled or wet linens in plastic bag and separating them from family laundry; washing with detergent and hot water	
Cleaning surfaces with bleach and water solution of 1:10 ratio, disinfecting toilet bowl or bedpan with full-strength bleach	
Preparing client's food in clean area; washing dishes and utensils in hot, soapy water—can be washed with the family dishes	

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Emphasize necessity of daily skin care, including inspecting skinfolds, pressure points, and perineum, and of providing adequate cleansing and protective measures such as ointments and padding.	Healthy skin provides barrier to infection. Measures to prevent skin disruption and associated complications are critical.
Ascertain that client/SO can perform necessary oral and dental hygiene. Review procedures, as indicated. Encourage regular dental care.	The oral mucosa can quickly exhibit severe, progressive complications; therefore, preventative and early intervention measures are essential.
Review dietary needs and ways to improve intake when anorexia, diarrhea, weakness, or depression interfere with intake.	Promotes nutrition necessary for overcoming effects of OIs and enhances feeling of well-being. Note: A good diet for a person with advanced HIV may not be the low-fat, low-calorie diet recommended for healthy people. When client is able to eat, he or she may need to take in more calories and protein to keep from losing muscle mass (a component of wasting syndrome). If client can eat, some of these foods may be helpful: instant breakfast drinks, eggs, peanut butter, cheeses, and anything client enjoys.
Review medication regimen, interactions, and side effects.	May increase probability of success with therapeutic regimen.
Provide information about and assist in developing a plan for symptom management that complements medical regimen; for example, client experiencing intermittent diarrhea should take diphenoxylate (Lomotil) before going to a social event.	Quality of life is an important issue in the management of symptoms of severe HIV infection, such as anemia, pain, fatigue, weakness, sleep disorders, GI symptoms, and/or the side effects of medications. Having a plan provides client with increased sense of control, reduces risk of embarrassment, and promotes comfort.
Emphasize importance of adequate rest.	Helps manage fatigue; enhances coping abilities and energy level.
Encourage activity and exercise at level that client can tolerate.	Stimulates release of endorphins in the brain, enhancing sense of well-being.
Emphasize necessity of continued healthcare and follow-up.	Provides opportunity for altering regimen to meet individual changing needs.
Recommend cessation of smoking.	Smoking increases risk of respiratory infections and can further impair immune system.
Identify signs and symptoms requiring medical evaluation: persistent fever or night sweats, swollen glands, continued weight loss, diarrhea, skin blotches or lesions, headache, and chest pain or dyspnea.	Early recognition of developing complications and timely interventions, within client's advance directives, may prevent untimely decline.
Identify community resources such as hospice or residential care centers, visiting nurse, home-care services, Meals on Wheels, and peer group support.	Facilitates transfer from acute care setting for recovery and independence of end-of-life care.

**POTENTIAL CONSIDERATIONS** in addition to the nursing diagnoses listed in the plan of care.

- **Grieving**—loss of significant object (e.g., job, status, significant others/family, processes of body)
- **ineffective Protection**—abnormal blood profile (e.g., anemia, thrombocytopenia, coagulation), inadequate nutrition, pharmaceutical agents (e.g., antineoplastic, immune), cancer
- **caregiver Role Strain**—illness severity of care receiver, increasing care needs, amount/complexity of activities, history of family dysfunction, lack of respite for caregiver, caregiver's competing role commitments

# RHEUMATOID ARTHRITIS (RA)

## I. Pathophysiology (Ruffing & Bingham, 2017; Smith & Brown, 2017; Zack, 2014)

- a. Rheumatoid arthritis is best characterized as an **immune-mediated inflammatory disease (IMID)**. Swelling of the small joints, especially in the hands and feet, is the hallmark of the disease, but most joints in the body can become affected. In addition to the joints, other manifestations of the disease can be seen, including subcutaneous nodules, eye inflammation, lowering of the white blood count, and lung disease.
- b. Disease patterns include spontaneous remission (in less than 10% of clients in first 6 months), intermittent painful exacerbation of symptoms, or persistent and progressive disease activity.
- c. RA causes joint damage in 80% to 85% of individuals, with the brunt of the damage occurring during the first 2 years of the disease.
- d. The joints involved most frequently are the proximal interphalangeal (PIP) and metacarpophalangeal (MCP) joints of the hands, the wrists, and small joints of the feet, including the metatarsophalangeal (MTP) joints. Shoulders, elbows, knees, and ankles are also affected in many people. With the exception of the cervical spine, the spine is unaffected.
- e. Neurological manifestations include peripheral neuropathies (e.g., usually in lower extremities; wrist [carpal tunnel] and feet [tarsal tunnel]).
- f. Inflammatory process can also affect the eyes, blood vessels, the pleural membrane of the lungs, or the pericardial sac.

## II. Stages (Rheumatoid Arthritis Network, 2017)

- a. Monocyclic progressive (also called remissive): one episode that ends within 2 to 5 years of initial diagnosis and does not recur. This may result from early diagnosis and/or aggressive treatment.

- b. Polycyclic progressive (also called intermittent): constant recurrence of RA symptoms and flares but in fluctuating stages

## III. Etiology (Ruffing & Bingham, 2017; Smith & Brown, 2017)

- a. Specific cause unknown
- b. Associated factors: genetic predisposition; possible infectious triggers, bacterial periodontal disease, autoimmune responses against citrullinated peptides detected as anticitrullinated peptide antibodies (ACPAs)
- c. Other possible factors: more common in females, with ratio to males approximately 3:1; hormone interaction; psychological stress; heavy, long-term smoking; history of blood transfusions

## IV. Statistics

- a. Morbidity: In 2017, an estimated 1.5 million U.S. adults are living with RA (Rheumatoid Arthritis Network, 2017). It has been estimated that approximately 40% become disabled after 10 years, but outcomes are highly variable. Other sources suggest that more than 50% remain fully employed, even after 10 to 15 years of disease, with one-third having only intermittent low-grade disease and another one-third experiencing spontaneous remission (Smith & Brown, 2017).
- b. Mortality: A recent study reported that rheumatoid arthritis significantly increased participants' overall risk of death (40% higher than in general population), especially due to respiratory or cardiovascular causes (Brigham & Women's Hospital, 2015). RA is also known to be associated with higher risks for lymphoma, anemia, osteoporosis, and depression (Ruffing & Bingham, 2017).
- c. Cost: Numerous sources suggest that per person direct costs are approximately \$30,000 annually for RA treatments, while indirect costs can range from \$1500 to \$22,000 annually (Rheumatoid Arthritis Support Network, 2016).

## G L O S S A R Y

**Arthrodesis (fusion):** Surgical procedure that involves removing the joint and fusing the bones into one immobile unit. Although the procedure limits movement, it can be useful for increasing stability and relieving pain in affected joints. The most commonly fused joints are the ankles and wrists and joints of the fingers and toes.

**Disease-modifying antirheumatic drugs (DMARDs):** A class of medications used in the treatment of RA; they often slow or stop the course of the disease to help prevent joint destruction.

**Pannus:** Inflamed synovial granulation tissue reflecting chronic RA.

**Raynaud's phenomenon:** Condition in which cold temperatures or strong emotions cause blood vessel spasms that block blood flow to the fingers, toes, ears, and nose. This causes intermittent pallor, cyanosis, and then redness before color returns to normal.

**Sjögren's syndrome:** Chronic disorder that causes insufficient moisture production in certain glands of the body. This leads to impaired secretion of saliva and tears and results in the sicca complex: dry mouth (xerostomia) and dry eyes (keratoconjunctivitis sicca). Secondary Sjögren's syndrome is often associated with other autoimmune disorders, including RA.

**Synovial fluid:** A thick, straw-colored substance found in small amounts in joints, bursae, and tendon sheaths.

**Synovial membrane:** Tissue that lines a joint.

**Synovitis:** Inflammation of the lining of a joint.

**Tendon reconstruction:** RA can damage and even rupture tendons, the tissues that attach muscle to bone. This surgery, which is used most frequently on the hands to restore function, reconstructs the damaged tendon by attaching an intact tendon to it.

## CARE SETTINGS

Client is treated at community level unless surgical procedure is required or medical complication occurs.

## RELATED CONCERNs

Psychosocial aspects of care, page 835

Total joint replacement, page 729

## CLIENT ASSESSMENT DATABASE

Data depend on severity and involvement of other organs (e.g., eyes, heart, lungs, kidneys), stage (i.e., acute exacerbation or remission), and coexistence of other forms of arthritis and autoimmune diseases.

DIAGNOSTIC DIVISION MAY REPORT	MAY EXHIBIT
<b>ACTIVITY/REST</b> <ul style="list-style-type: none"> <li>• Joint swelling (hallmark for RA required for diagnosis)</li> <li>• Joint pain and tenderness, usually symmetrical, worsened by movement</li> <li>• Morning stiffness often lasting 1 hour or more and that does not improve with movement</li> <li>• Generalized weakness (possible effect of anemia)</li> <li>• Functional limitations affecting desired lifestyle, leisure time, and occupation</li> <li>• Fatigue; sleep disturbances</li> </ul>	<ul style="list-style-type: none"> <li>• Impaired ROM of joints, particularly hands—fingers and wrist, hips, knees, ankles, elbows, and shoulder</li> <li>• Joint deformities</li> <li>• Altered gait and posture</li> <li>• Muscle weakness, contractures, and atrophy</li> </ul>
<b>EGO INTEGRITY</b> <ul style="list-style-type: none"> <li>• Threat to self-concept, body image, and personal identity</li> <li>• Acute and/or chronic stress factors, including financial, employment, disability, and relationship</li> <li>• Hopelessness and powerlessness over incapacitating situation</li> </ul>	<ul style="list-style-type: none"> <li>• Dependence on others</li> </ul>
<b>FOOD/FLUID</b> <ul style="list-style-type: none"> <li>• Inability to consume adequate food and fluids (temporoman-dibular joint [TMJ] involvement)</li> <li>• Anorexia, nausea</li> </ul>	<ul style="list-style-type: none"> <li>• Weight loss</li> <li>• Dryness of oral mucous membranes, decreased oral secretions, and dental caries</li> </ul>
<b>HYGIENE</b> <ul style="list-style-type: none"> <li>• Varying degrees of difficulty performing self-care activities</li> <li>• Dependence on others</li> </ul>	
<b>NEUROSENSORY</b> <ul style="list-style-type: none"> <li>• Numbness, tingling of hands and feet</li> <li>• Loss of sensation or burning in fingers</li> </ul>	<ul style="list-style-type: none"> <li>• Symmetrical joint swelling</li> </ul>
<b>PAIN/DISCOMFORT</b> <ul style="list-style-type: none"> <li>• Acute episodes of pain that may or may not be accompanied by soft tissue swelling in joints</li> <li>• Symmetrical pattern of pain involving joints on both sides of the body</li> <li>• Chronic aching pain and stiffness with mornings most difficult</li> <li>• Pain limiting ability to perform tasks, such as lifting, using hands, or walking</li> </ul>	<ul style="list-style-type: none"> <li>• Red, swollen, hot joints (during acute exacerbations)</li> </ul>
<b>SAFETY</b> <ul style="list-style-type: none"> <li>• Persistent low-grade fever</li> <li>• Dryness of eyes and mucous membranes</li> <li>• Difficulty managing homemaker or maintenance tasks</li> <li>• History of smoking (<i>Note:</i> A number of studies have demonstrated that cigarette smoking is a significant risk factor for the development of RA and also implicated in disease severity) (Ruffing &amp; Bingham, 2017).</li> </ul>	<ul style="list-style-type: none"> <li>• Pale, shiny, taut skin</li> <li>• Skin problems, especially under nails, or skin rash, ulcers, blisters (reflects a more serious case of RA in general)</li> <li>• Subcutaneous rounded, nontender nodules on pressure points of elbows, feet, knees</li> <li>• Decreased muscle strength, altered gait, reduced ROM</li> </ul>
<b>SEXUALITY</b> <ul style="list-style-type: none"> <li>• Difficulty engaging in sexual activity as desired; abstinence</li> <li>• Risk for pregnancy complications</li> </ul>	

(continues on page 826)

## CLIENT ASSESSMENT DATABASE (contd.)

### MAY REPORT (continued)

### MAY EXHIBIT (continued)

#### SOCIAL INTERACTION

- Impaired interactions with family and others
- Change in roles, responsibilities
- Isolation

#### TEACHING/LEARNING

- Familial history of RA (in juvenile onset) **P**
- Higher risk of heart and lung disorders, including pericarditis, valvular lesions, pulmonary fibrosis, pleuritis
- Use of health foods, vitamins, untested arthritis “cures”

#### DISCHARGE PLAN CONSIDERATIONS

- May require assistance with transportation, self-care activities, homemaker/maintenance tasks, and changes in physical layout of home

► Refer to section at end of plan for postdischarge considerations.

#### DIAGNOSTIC STUDIES

##### TEST

##### WHY IT IS DONE

##### WHAT IT TELLS ME

#### BLOOD TESTS

- **Rheumatoid factor (RF):** Macroglobulin type of antibody found in blood of individuals with RA. RF antibodies are usually immunoglobulin (Ig) M but may also be IgG or IgA (Van Leeuwen & Bladh, 2015).

Rheumatoid factor is not specific for the diagnosis of RA (seen in many other inflammatory and autoimmune conditions), although the test is most useful when there is a moderate level of suspicion for RA. *Note:* <50% are positive within the first 6 months. Only 80% to 85% of clients are ever positive. High titer in early RA is associated with a worse prognosis (Pope, 2016).

- **Inflammatory markers:**

- **Cyclic citrullinated peptide antibody test (also called anti-CCP [ACCP]):** Useful in early detection of RA.
- **Antinuclear antibody (ANA) titer:** Presence of ANA indicates presence of collagen vascular and immune complex disorders such as RA.
- **C-reactive protein (CRP):** Glycoprotein produced by the body in response to inflammation.
- **Complement C<sub>3</sub> and C<sub>4</sub>:** Act as enzymes that aid in the immunologic and inflammatory response and are used to detect autoimmune disease.
- **Complete blood count (CBC):** Battery of screening tests, which typically includes hemoglobin (Hgb); hematocrit (Hct); RBC count and morphology, indices, and distribution width index; platelet count and size; white blood cell (WBC) count and differential.

More specific marker for RA. If both anti-CCP and rheumatoid factor (RF) are positive, it is likely the client has a more severe form of the disease.

If high levels ANA are present, it could indicate a higher risk of developing an autoimmune disorder. Follow-up tests are needed to pinpoint/diagnose the specific rheumatic disorder. May be elevated with RA but is not specific to RA.

C<sub>3</sub> and C<sub>4</sub> are increased in acute-onset RA. Normal C<sub>4</sub> and decreased C<sub>3</sub> may be present in chronic RA (Van Leeuwen et al, 2015). Immune disorder or exhaustion results in depressed total complement levels.

Hgb may be decreased, revealing anemia, which is a common problem in clients with RA (Ruffing & Bailey, 2017). Platelet count may be elevated when inflammation is present or low because of certain medications. WBCs are elevated when infectious processes are present.

**WHY IT IS DONE** (continued)**WHAT IT TELLS ME** (continued)**OTHER DIAGNOSTIC STUDIES**

- **X-rays/radiographs:** Identify early indicators of RA and changes over time.
- **Joint ultrasound, Doppler ultrasonography (PDUS), quantitative ultrasound (QUS):** Uses high-energy sound waves bounced off internal tissues to detect arthritis by identifying the presence of fluid in the joints.
- **Computed tomography (CT) scan:** X-ray procedure that produces cross-sectional images of the body layer by layer.
- **Magnetic resonance imaging (MRI):** Diagnostic technique that provides cross-sectional images of structures within the body without x-ray or other forms of radiation.
- **Direct arthroscopy:** Surgical technique where a scope with camera is inserted into a joint to inspect, diagnose, and repair tissues.
- **Synovial fluid aspirate:** Needle aspiration of joint fluid to note volume, clarity, and presence of cells (red and white cells), crystals, and bacteria to aid in diagnosing joint-related problems and determining treatment options.

Reveals soft tissue swelling, erosion of bone, destruction of cartilage, osteoporosis of adjacent bone, and progression to bone cyst formation, narrowing of joint space, and subluxation. Concurrent osteoarthritic changes may also be noted.

Can reveal joint inflammation before x-rays show damage and document early evidence of RA. PDUS may be reliable for monitoring inflammatory activity in the joint. QUS, which is used for osteoporosis, can detect bone loss in fingers, which may prove to be a good indicator of early RA.

Provides preoperative assessment as to the main indications for surgical intervention, namely, neurological deficit and severe pain. MRI can detect early inflammation in the hands before it is even visible on x-ray and is particularly accurate at pinpointing synovitis.

Visualization of area reveals bone irregularities and degeneration of joint.

May reveal volume greater than normal; may be opaque, cloudy, or yellow due to inflammatory response, bleeding, or degenerative waste products. WBCs and leukocytes are increased, whereas viscosity and complement ( $C_3$  and  $C_4$ ) are decreased.

**NURSING PRIORITIES**

1. Alleviate pain.
2. Increase mobility.
3. Promote positive self-concept.
4. Support independence.
5. Provide information about disease process, prognosis, and treatment needs.

**DISCHARGE GOALS**

1. Pain relieved or controlled.
2. Dealing realistically with current situation.
3. Managing activities of daily living (ADLs) by self or with assistance, as appropriate.
4. Disease process, prognosis, and therapeutic regimen understood.
5. Plan in place to meet needs after discharge.

**NURSING DIAGNOSIS:** acute/chronic Pain**May Be Related To**

Physical injury agent—accumulation of fluid/inflammatory process (e.g., swelling, damage/destruction of joint; extraarticular nodules)

Alteration in sleep pattern; fatigue

**Possibly Evidenced By**

Self-report of intensity and characteristics of pain using standardized instrument

Narrowed focus; self-focused

Expressive behavior (e.g., restlessness, irritability)

Guarding behavior; protective behavior

Changes in vital signs (acute)

Alteration in ability to continue previous activities

**Desired Outcomes/Evaluation Criteria—Client Will****Pain Control NOC**

Report pain is relieved or controlled.

Follow prescribed pharmacological regimen.

Incorporate relaxation skills and diversional activities into pain control program.

**Pain: Disruptive Behaviors NOC**

Appear relaxed and able to sleep or rest appropriately.

Participate in activities of daily living at level of ability.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Pain Management NIC</b>	
<b>Independent</b>	
Investigate reports of pain, noting location and intensity using a 0 to 10 (or similar) scale. Note precipitating factors and nonverbal pain cues.	Self-report should be the primary source of pain assessment in determining pain management needs and effectiveness of program.
Suggest client assume position of comfort while in bed or sitting in chair. Promote bedrest when indicated, but resume movement as soon as possible.	In severe disease or acute exacerbation, total bedrest may be necessary until objective and subjective improvements are noted to limit pain and injury to joint. Note: Immobility is known to worsen arthritis pain and stiffness.
Place and monitor use of pillows, sandbags, trochanter rolls, splints, and orthotics.	Stabilizes joint, decreasing joint movement and associated pain. Note: Orthotic devices play an important role in rehabilitation management to decrease pain and inflammation, improve function, reduce deformity, and correct biomechanical malalignment.
Encourage frequent changes of position.	Prevents general fatigue and joint stiffness.
Recommend that client take warm bath or shower on arising and/or at bedtime. Apply warm, moist compresses to affected joints several times a day. Monitor water temperature.	Heat promotes muscle relaxation and mobility, decreases pain, and relieves morning stiffness. Note: Sensitivity to heat may be diminished and dermal injury may occur.
Provide gentle massage.	Promotes relaxation and reduces muscle tension.
Encourage use of stress management techniques, such as progressive relaxation, biofeedback, visualization, guided imagery, self-hypnosis, and controlled breathing. Provide Therapeutic Touch, if desired.	Promotes relaxation, provides sense of control, and may enhance coping abilities.
Involve client in diversional activities appropriate for individual situation.	Refocuses attention, provides stimulation, and enhances self-esteem and feelings of general well-being.
Medicate before planned activities and exercises, as indicated.	Promotes relaxation, reduces muscle tension and spasms, facilitating participation in therapy.
<b>Collaborative</b>	
Administer medications, as indicated, for example:	Because irreversible joint damage occurs within the first 2 years, early diagnosis and intervention are necessary. Medications are the mainstay of treatment with a goal of (1) managing pain, (2) slowing joint destruction, and (3) preserving joint function.
Analgesics: NSAIDs, such as aspirin and acetaminophen (Tylenol Arthritis, Panadol); ibuprofen (Advil, Motrin); naproxen (Aleve); meloxicam (Mobic), etodolac (Lodine), and nabumetone (Relafen); diclofenac (Voltaren); oxaprozin (Daypro)	These drugs control mild to moderate pain and inflammation by inhibition of prostaglandin synthesis and allow for improvement in mobility and function.
COX-2 inhibitors, such as celecoxib (Celebrex)	The NSAID class of COX-2 inhibitors is also effective in controlling inflammation. However, Celebrex is the only one currently available in the United States due to Food and Drug Administration (FDA) findings of potential for adverse cardiovascular side effects with other COX-2 drugs.
Disease-modifying antirheumatic drugs (DMARDs), such as:	Although both NSAIDs and DMARDs improve symptoms of active RA, only DMARDs have been shown to alter the disease course (e.g., decreases disease severity, disability, and mortality).
Methotrexate (Rheumatrex, Trexall), sulfasalazine (Azulfidine), leflunomide (Arava), certolizumab pegol (Cimzia), golimumab (Simponi), abatacept (Orencia), rituximab (Rituxan), tocilizumab (Actemra), anakinra (Kineret), hydroxychloroquine (Plaquenil), sulfasalazine (SSZ), minocycline	Methotrexate is considered the first-line DMARD agent for most individuals with RA. Note: Current DMARD therapy typically includes combinations of two or three drugs, most of which are methotrexate based (e.g., methotrexate + hydroxychloroquine or methotrexate + hydroxychloroquine + sulfasalazine) (Pope, 2016; Ruffing & Bingham, 2017; Singh et al, 2012).

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Anti-tumor necrosis factor (anti-TNF) agents (e.g., adalimumab [Humira], etanercept [Enbrel], infliximab [Remicade]). And non-tumor necrosis factor (non-TNF) biologics (e.g., abatacept [Orencia], rituximab [Rituxan], tocilizumab [Actemra]; sarilumab [Kevzara])	Tumor necrosis factor (TNF) is a proinflammatory cytokine produced by the immune system. Anti-TNFs reduce TNF to control inflammation and have been used for more than 10 years to treat inflammatory conditions. Given by injection or infusion, these drugs are able to stop disease progression. Non-TNFs use other mechanisms to interrupt the inflammatory autoimmune response. Note: Patients who have an inadequate response to a first-line antitumor TNF drug may experience a better response with non-TNF-targeted drugs (Garcia, 2016). Because of the effect of these drugs on the immune system, the client is at greater risk for infections. Therefore, screening for TB is recommended for all clients who are beginning or currently receiving biologic agents. And vaccinations are recommended for all clients taking DMARDs or biologic agents: pneumococcal, influenza, hepatitis B, human papillomavirus (HPV), and herpes zoster (Singh et al, 2012).
Immunomodulatory and cytotoxic agents, such as azathioprine (Imuran) and cyclosporine (Neoral)	Immune suppressants may be used for treatment of severe cases of RA when other medications have failed.
Corticosteroids, such as prednisone (Deltasone) and methylprednisolone (Medrol)	These drugs have both anti-inflammatory and immunoregulatory activity and are useful in early disease as temporary adjunctive therapy. Corticosteroids may be used as a bridge while waiting for DMARDs to work. In addition, cortisone may be injected directly into a joint space to provide localized reduction of inflammation without systemic overloading.
Assist with physical therapies, such as paraffin gloves or whirlpool baths.	Provides sustained heat to reduce pain and improve ROM of affected joints.
Apply ice or cold packs when indicated.	Cold may relieve pain and swelling during acute episodes.
Instruct in use and monitor effect of transcutaneous electrical nerve stimulator (TENS) unit, if used.	Constant low-level electrical stimulus blocks transmission of pain sensations.
Prepare for surgical interventions, such as tendon realignment and repair, tunnel release procedures, total joint replacement, joint fusion.	Corrective surgical procedures may be indicated to reduce pain and/or improve joint function and mobility.

## NURSING DIAGNOSIS: impaired physical Mobility

### May Be Related To

Musculoskeletal impairment; joint stiffness  
Pain; reluctance to initiate movement

### Possibly Evidenced By

Decrease in range of motion, fine motor skills; slowed movement  
Alteration in gait; difficulty turning

### Desired Outcomes/Evaluation Criteria—Client Will

#### Joint Movement NOC

Maintain or increase function of affected joint(s).  
Maintain position of function with absence of contractures.

#### Ambulation NOC

Engage in techniques or behaviors that enhance ability to ambulate.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Exercise Therapy: Joint Mobility NIC</b>	
<b>Independent</b>	
Evaluate and then continuously monitor degree of joint inflammation and pain.	Level of activity and exercise depends on progression or resolution of inflammatory process.
Maintain bedrest or chair rest when indicated. Schedule activities providing frequent rest periods and uninterrupted nighttime sleep.	Person with RA needs a good balance between rest and exercise, with more rest when disease is active and more exercise when it is not. Systemic rest is mandatory during acute exacerbations and important throughout all phases of disease to reduce fatigue and improve strength.
Assist with active or perform passive ROM and resistive exercises and strengthening exercises when able.	Maintains and may improve joint function, muscle strength, and general stamina. Note: Inadequate exercise leads to joint stiffening, whereas excessive activity can damage joints.
Discuss and provide safety needs, such as raised chairs and toilet seat, use of handrails in tub or shower and toilet, proper use of mobility aids, or wheelchair safety.	Helps prevent accidental injuries and falls.
<b>Positioning NIC</b>	
Reposition frequently using adequate personnel if hospitalized client is unable to walk.	Proper transfer techniques prevent shearing abrasions of skin. Repositioning relieves pressure on sensitive tissues and promotes circulation.
Demonstrate and assist with transfer techniques and use of mobility aids, such as walker, cane, or bed trapeze.	Facilitates self-care and client's independence.
Position with supports such as pillows, sandbags, or trochanter roll. Provide joint support with splints.	Promotes joint stability, reducing risk of injury, and maintains proper joint position and body alignment, minimizing contractures.
Suggest using small or thin pillow under neck.	Prevents flexion of neck, when client has RA of the cervical spine.
<b>Collaborative</b>	
Collaborate in treatment of underlying condition causing pain and dysfunction.	To maximize optimal level of function and prevent complications.
Recommend or provide pressure-reducing mattress.	Decreases pressure on fragile tissues to reduce risks of immobility and development of decubitus ulcers.
<b>Exercise Therapy: Joint Mobility NIC</b>	
Consult with physical and occupational therapists and vocational specialist.	Helps with formulating exercise and activity program based on individual needs in identifying and reducing impairments in ROM, flexibility, strength, and endurance, and to instruct in joint protection strategies and mobility devices and adjuncts.
<b>Self-Care Assistance: Instrumental Activities of Daily Living (IADLs) NIC</b>	
Determine appropriateness of, and ability to use, scooter or special enhancements to automobile such as hand controls and wide mirrors.	Facilitates movement within the environment, decreases fatigue, and promotes independence.

#### NURSING DIAGNOSIS: risk for ineffective Role Performance

##### Possibly Evidenced By

Pain; fatigue, depression  
 Insufficient resources (e.g., financial, social, knowledge)  
 Stressors; conflict; insufficient support system; powerlessness  
 Change in self-/other's perception of role, or incapacity to resume role

**NURSING DIAGNOSIS:** **risk for ineffective Role Performance** (continued)**Desired Outcomes/Evaluation Criteria—Client Will****Role Performance NOC**

Talk with family/employer about changes or limitations imposed by condition.  
 Verbalize acceptance of self in changed role.  
 Formulate realistic plans for adapting to role change.  
 Maintain safe, health-promoting environment.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Role Enhancement NIC</b>	
<i>Independent</i>	
Identify the client at risk and ascertain how client views self in usual lifestyle functioning, including home, employment, and sexual aspects, as indicated.	Although RA can develop in anyone, regardless of age or gender, it typically strikes women between the ages of 30 and 60. This age range necessarily means that RA can impact many life events and quality of life.
Encourage verbalization between client/SO about concerns of disease process and future expectations.	Provides opportunity to identify fears or misconceptions and deal with them directly.
Discuss meaning of change to client and SO as appropriate.	Identifying how illness can affect perception of self and interactions with others will determine need for further intervention or counseling.
Discuss client's perception of how SO perceives limitations.	Verbal and nonverbal cues from SO may have a major impact on how client views self.
Acknowledge and accept feelings of grief, hostility, and potential dependency.	Constant pain is wearing, and feelings of anger and hostility are common. Acceptance provides feedback that feelings are normal.
Note withdrawn behavior, use of denial, or overconcern with changes.	May suggest emotional exhaustion or maladaptive coping methods, requiring more in-depth intervention and psychological support.
Assist client to identify positive behaviors that will aid in coping.	Helps client maintain self-control, enhancing self-esteem.
Involve client in planning care and scheduling activities.	Enhances feelings of competency and self-worth and encourages independence and participation in therapy.
Encourage SO/family to identify ways to assist client in meeting child care/household/home maintenance duties as needed to maintain a clean, safe, and healthy environment.	Advance planning helps ensure that needs will be met on an ongoing basis as client's condition and ability to perform usual role fluctuate.
<i>Collaborative</i>	
Identify local and national support groups, disability advocate as appropriate.	Provides role models and assistance with problem-solving and adapting to changes as they occur. Disability advocates provide additional support when dealing with problems within the community.
Recommend vocational/employment counselors as indicated.	Employment counselors provide client with information regarding available assistive devices and appropriate worksite accommodations or modifications.
Coordinate home evaluation by occupational therapist and rehabilitation team as indicated.	Helpful in identifying potential or existing health and safety hazards and to determine adaptations that may be required (e.g., chair or stair lifts, wheelchair-accessible doors and hallways, clean water available, timely trash removal).
Identify community resources, such as visiting nurse, homemaker service, social services, senior citizens' groups, or sources for necessary home repairs or modifications.	Can facilitate transfer to, and support continuation in, safe home setting.
Refer to counseling, such as psychiatric clinical nurse specialist, psychiatrist/psychologist, or social worker.	Client/SO may require ongoing support to deal with long-term debilitating process.
Administer medications as indicated, such as antianxiety and mood-elevating drugs.	May be needed in presence of severe depression until client develops more effective coping skills.

**NURSING DIAGNOSIS:** **Self-Care deficit (specify)****May Be Related To**

Musculoskeletal impairment; pain, discomfort  
Fatigue; weakness

**Possibly Evidenced By**

Inability to manage ADLs—feeding, bathing, dressing, and/or toileting

**Desired Outcomes/Evaluation Criteria—Client Will****Self-Care: Status NOC**

Perform self-care activities at a level consistent with individual capabilities.  
Demonstrate techniques and lifestyle changes to meet self-care needs.  
Identify personal and community resources that can provide needed assistance.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Self-Care Assistance NIC</b>	
<i>Independent</i>	
Determine usual level of functioning using Functional Level Classification 0–4 for status before onset or exacerbation of RA and anticipated changes.	Identifies degree of assistance and support required. For example, the level 0 client is able to perform usual ADLs, including self-care, vocational, and avocational, whereas the level 4 client is limited in all these areas and does not participate in activity.
Assess barriers to participation in self-care. Identify and plan for personal assistance and environmental modifications.	Prepares client for increased independence, which enhances self-esteem.
Perform or assist client with meeting client's needs.	Personal care is part of nursing care and should not be neglected while self-care independence is promoted and integrated.
Maintain mobility, pain management, and exercise programs.	Supports physical and emotional independence.
Allow client sufficient time to complete tasks to fullest extent of ability. Capitalize on individual strengths.	May need more time to complete tasks by self but provides an opportunity for greater sense of self-confidence and self-worth.
Identify sources for necessary assistive devices and equipment such as lifts, safety bars, elevated toilet seat, wheelchair, scooter.	Provides opportunity to acquire equipment before discharge.
Discuss client's/SO's perception of current environmental needs and ability to maintain safe surroundings.	Determines feasibility of changing home layout or access (e.g., doors may need to be larger; ramp may be needed) to meet individual needs.
Determine financial resources to meet needs of individual situation. Identify support systems available to client, such as extended family, friends, and neighbors.	Availability of personal resources and community supports will affect ability to problem-solve and choice of solutions.
<i>Collaborative</i>	
Consult with/refer to rehabilitation specialists.	Helpful in determining/obtaining assistive and adaptive devices to meet individual needs.
Arrange for consult with other agencies, such as Meals on Wheels, home-care service, or nutritionist.	May need additional kinds of assistance to continue in home setting.

**NURSING DIAGNOSIS:** **risk for ineffective Health Management****Possibly Evidenced By**

Difficulty managing complex treatment regimen; perceived barrier/benefit; insufficient knowledge of therapeutic regimen  
Excessive demands (e.g., family, employment)  
Insufficient social support; economically disadvantaged

**NURSING DIAGNOSIS:** **risk for ineffective Health Management** (continued)**Desired Outcomes/Evaluation Criteria—Client Will****Self-Management: Chronic Disease NOC**

Verbalize understanding of condition, prognosis, and potential complications.

Verbalize understanding of therapeutic needs.

Demonstrate behaviors and changes in lifestyle necessary to maintain therapeutic regimen.

Develop a plan for self-care, including lifestyle modifications consistent with mobility and/or activity restrictions.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Teaching: Disease Process NIC</b>	
<i>Independent</i>	
Review disease process, prognosis, and future expectations.	Provides knowledge base from which client can make informed choices.
Discuss client's role in management of disease process through nutrition, medication, and balanced program of exercise and rest.	Goal of disease control is to suppress inflammation in joints and other tissues to maintain joint function and prevent deformities.
Assist in planning a realistic and integrated schedule of activity, rest, personal care, drug administration, physical therapy, and stress management.	Provides structure and defuses anxiety when managing a complex chronic disease process.
Identify individually appropriate exercise program components, such as swimming, stationary bike, or nonimpact aerobics.	Can increase client's energy level and mental alertness and minimize functional limitations. Program needs to be customized based on joints involved and client's general condition to maximize effect and reduce risk of injury.
Emphasize importance of continued pharmacotherapeutic management.	Benefits of drug therapy depend on correct regimen, dosage, timing, and continuation without gaps.
Recommend use of enteric-coated or buffered aspirin or nonacetylated salicylates, such as choline salicylate (Arthropan) or choline magnesium trisalicylate (Trilisate).	These preparations, ingested with food, minimize gastric irritation, reducing risk of gastric bleeding. Note: Non-acetylated products have a longer half-life, requiring less frequent administration in addition to producing less gastric irritation.
Suggest taking medications, such as NSAIDs, with meals, milk products, or antacids and at bedtime.	Limits gastric irritation. Reduction of pain at bedtime enhances sleep and increased blood level decreases early morning stiffness.
Emphasize importance of reading product labels and refraining from over-the-counter (OTC) drug usage without prior medical approval.	Many products, such as cold remedies or antidiarrheals, contain hidden salicylates that increase risk of harmful side effects.
Review importance of balanced diet with foods high in vitamins, protein, and iron.	Promotes general well-being and tissue repair or regeneration.
Encourage overweight client to lose weight and supply with weight reduction information, as appropriate.	Weight loss reduces stress on joints, especially hips, knees, ankles, and feet.
Provide information about and resources for assistive devices, such as wheeled dolly or wagon for moving items, pickup sticks, lightweight dishes and pans, raised toilet seat, and safety handlebars.	Reduces force exerted on joints and enables individual to participate more comfortably in needed or desired activities.
Discuss energy-saving techniques, such as sitting instead of standing to prepare meals, shower, shave, or apply makeup.	Prevents fatigue; facilitates self-care and independence.
Encourage maintenance of correct body position and posture both at rest and during activity—keeping joints extended, not flexed, wearing splints for prescribed periods, avoiding remaining in a single position for extended periods, positioning hands near center of body during use, and sliding rather than lifting objects when possible.	Good body mechanics must become a part of client's lifestyle to lessen joint stress and pain.

(continues on page 834)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Review safety issues related to mobility devices, especially electric scooters. Suggest use of a pennant when traveling on open streets.	Ability to travel over uneven surfaces, gravel, or soft ground is dependent upon specific scooter model. In addition, speed and safe maneuvering are equally important for the driver and other individuals in the vicinity. A pennant can be seen by other motorists.
Review necessity of frequent inspection of skin and meticulous skin care under splints, casts, and supporting devices. Demonstrate proper padding.	Reduces risk of skin irritation and breakdown.
Discuss necessity of medical follow-up and laboratory studies.	Drug therapy requires frequent assessment and refinement to ensure optimal effect and to prevent overdose or dangerous side effects.
Provide for sexual and childbirth counseling, as necessary.	Information about different positions and techniques and/or other options for sexual fulfillment may enhance personal relationships and feelings of self-worth and self-esteem. Note: A large number of clients with RA are in childbearing years and need counseling, support, and medical interventions.
Identify community resources, such as chapters of the National Institute of Arthritis and Muscular and Skin Diseases (NIAMS) and the Arthritis Foundation.	Assistance and support from others promote maximal recovery.

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

- **Fatigue**—disease state, poor physical condition, stress, depression
- **chronic Pain**—chronic physical disability
- **impaired physical Mobility**—pain, joint stiffness, disuse, decreased endurance, reluctance to initiate movement
- **Self-Care deficit**—pain, musculoskeletal impairment, weakness, fatigue, environmental barriers

## General

### PSYCHOSOCIAL ASPECTS OF CARE

#### I. Mind-Body-Spirit Connection

- a. When a physiological response occurs, there is a corresponding psychological response (Anandarajah & Hight, 2001).
  - i. Emotional instability associated with steroid therapy or Cushing's syndrome
  - ii. Irritability of hypoglycemia
  - iii. Anxiety associated with impaired oxygenation
- b. Emotional response during illness is of extreme importance.
  - i. The stress of illness is well recognized; however, the effect on the individual is unpredictable.
  - ii. The client's perception of, and response to, the event may result in unmet psychological needs that drain energy resources needed for healing.
  - iii. Values brought to the interactions between clients, families, and healthcare providers affect the care that a client expects and receives.

**II. Psychoneuroimmunology**—(PNI) provides new information about how interactions between the mind and the neuroendocrine and immune systems influence health and healing.

- a. Negative emotions or stressful experiences can intensify health threats, contribute to prolonged infection, and result in delayed healing (Kiecolt-Glaser et al, 2002).
  - i. Chronic stress: decreased T and B cells, decreased natural killer (NK) cells, increased blood levels of Epstein-Barr virus
  - ii. Depression: decreased T cells, decreased number and function of lymphocytes, decreased NK cells
  - iii. Grieving: decreased lymphocyte proliferation
- b. Positive emotions can enhance immune response, facilitate healing, and slow disease progression.
  - i. Personal sharing of traumatic experience: increased lymphocyte response
  - ii. Support group intervention: increased NK cells and activity, increased lymphocyte count
  - iii. Humor and laughter: increased immunoglobulin A, increased lymphocyte count and activity

#### G L O S S A R Y

**Active-listening:** Reflecting the underlying feelings in the message that is heard.

**Eye movement desensitization and reprocessing (EMDR):** Information-processing psychotherapy technique that integrates elements of psychodynamic, cognitive-behavioral, interpersonal, experiential, and body-centered therapies to assist individuals to deal with anxious feelings and stress associated with traumatic memories.

**Guided imagery:** Method of helping an individual relax by means of guiding him or her in a vision of tranquil places.

**I-messages:** Expression of feelings stated as "I feel . . ." in a nonblameful way.

**Implosive therapy (flooding):** The individual is "flooded" with a continuous presentation of the phobic stimulus until it no longer elicits anxiety.

**Labile affect:** Excessive emotional reactivity associated with frequent changes or swings in emotions and mood.

**LGBTQ:** Lesbian, gay, bisexual, transgender, queer or questioning.

**Locus of control:** Site of control in an individual, which may be internal or external.

**Mindfulness:** Method of staying in the moment.

**Natural killer (NK) cells:** Cytotoxic lymphocytes play a major role in suppressing cancer cells and killing cells infected by viruses.

**Psychoneuroimmunology (PNI):** Field of study that focuses on relationship between psychosocial processes and nervous, endocrine, and immune system functioning.

**Psychosocial:** Theory of development proposed by Eric Erickson (1963).

**Religiosity:** Excessive demonstration of or obsession with religious ideas and behavior.

**Tapping:** A healing method using ancient Chinese acupressure and modern psychology (Ortner, 2013).

**Therapeutic Touch:** Method of healing by use of the hands moving through the energy field.

## CARE SETTING

Any setting in which nursing contact occurs and care is provided.

## RELATED CONCERNS

This is an aspect of all care and plans of care.

ASSESSMENT FACTORS TO BE CONSIDERED	
SUBJECTIVE	OBJECTIVE
<b>INDIVIDUAL</b> <ul style="list-style-type: none"><li>• Level of knowledge and education, how the individual accesses and incorporates information—auditory, visual, kinesthetic</li><li>• Religious affiliation—church attendance, importance of religion in client's life, belief in life after death</li><li>• Perception of body and its functions in health, illness, current situation</li><li>• Past experience with illness, hospitalization, and healthcare systems</li><li>• Emotional reactions in feeling (sensory) terms, for example, client states, "I feel scared"</li></ul>	<ul style="list-style-type: none"><li>• Age and gender (LGBTQ)</li><li>• Client's dominant language, literacy, knowledge and use of other languages, style of speech</li><li>• Patterns of communication with significant others (SOs), with healthcare givers</li><li>• How is client experiencing illness versus what illness actually is</li><li>• Emotional response to current treatment or hospitalization</li><li>• Behavior when anxious, afraid, impatient, withdrawn, or angry</li></ul>
<b>SIGNIFICANT OTHERS (SOs)</b> <ul style="list-style-type: none"><li>• Marital status, SOs, nuclear and extended family, recurring or patterned relationships</li><li>• Client's role in family tasks and functions</li><li>• How are SOs affected by the illness and prognosis?</li><li>• Lifestyle preferences to be considered: dietary, spiritual, sexual preference, other community—religious order, commune, retirement center</li></ul>	<ul style="list-style-type: none"><li>• Family development cycle—just married; young, adolescent children, leaving or returning home; retired</li><li>• Interaction processes within the family may or may not be supportive.</li></ul>
<b>SOCIOECONOMIC</b> <ul style="list-style-type: none"><li>• Employment; finances</li><li>• Environmental factors—residence, work, and recreation; out of usual environment such as on vacation, visiting</li></ul>	<ul style="list-style-type: none"><li>• Social class, value system, LGBTQ</li><li>• Social acceptability of disease or condition—sexually transmitted infections (STIs), HIV, obesity, substance abuse</li></ul>
<b>CULTURAL</b> <ul style="list-style-type: none"><li>• Ethnic background, heritage, and residence or locale</li><li>• Beliefs regarding caring and curing</li><li>• Values related to health and treatment</li><li>• Cultural factors related to illness in general and to pain response</li></ul>	<ul style="list-style-type: none"><li>• Health-seeking behaviors, illness referral system</li></ul>
<b>DISEASE (ILLNESS)</b> <ul style="list-style-type: none"><li>• Kind and cause of illness; how has it been treated and how should it be treated?</li><li>• Anticipated response to treatment; client's and SO's expectations</li><li>• If terminal illness, what do the client and SO know and anticipate?</li></ul>	<ul style="list-style-type: none"><li>• Is this an acute or chronic condition, is it inherited, what is the threat to self or others?</li><li>• Is the condition "appropriate" to the afflicted individual, for example, multiple sclerosis, diabetes mellitus (DM), cancer? (Note: Some theories suggest certain personalities are more prone to certain illnesses.) (Jongeward &amp; James, 1996)</li><li>• Illness related to personality factors, such as type A (may be myth or valid relative to management of stressors); high-risk behaviors</li></ul>
<b>NURSE RELATED</b> <ul style="list-style-type: none"><li>• Basic knowledge of human responses and how the current situation is related to response of the individual</li><li>• Basic knowledge of biological, psychological, social, cultural, and religious issues</li></ul>	<ul style="list-style-type: none"><li>• Knowledge and use of therapeutic communication skills</li><li>• Willingness to look at own behavior in relation to interaction with others and make changes as necessary</li></ul>

SUBJECTIVE (continued)	OBJECTIVE (continued)
<ul style="list-style-type: none"> <li>Knowledge of own value and belief systems, including prejudices and biases</li> </ul>	<ul style="list-style-type: none"> <li>Respect of client's privacy, confidentiality, human needs</li> </ul>

**NURSING PRIORITIES**

- Encourage effective coping skills of client and SO.
- Reduce emotional distress.
- Facilitate integration of self-concept and body-image changes.
- Support grieving process.
- Promote safe environment and client well-being.

**DISCHARGE GOALS**

- Client and family dealing realistically with current situation.
- Anxiety or fear manageable.
- Progressing through stages of grieving.
- Safe environment maintained.
- Plan in place to meet needs after discharge.

**NURSING DIAGNOSIS:** **ineffective Coping****May Be Related To**

Situational crises; high degree of threat  
 Disturbance in pattern of appraisal of threat  
 Inadequate tension release strategies  
 Inadequate resources  
 Gender differences in coping strategies

**Possibly Evidenced By**

Alteration in concentration; difficulty organizing information  
 Ineffective coping strategies  
 Change in communication pattern  
 Fatigue

**Desired Outcomes/Evaluation Criteria—Client Will****Coping NOC**

Identify ineffective coping behaviors and consequences.  
 Verbalize awareness of own coping and problem-solving abilities.  
 Meet psychological needs as evidenced by appropriate expression of feelings, identification of options, and use of resources.

**Decision-Making NOC**

Make decisions and express satisfaction with choices.

**ACTIONS/INTERVENTIONS****RATIONALE****Coping Enhancement NIC***Independent*

Review pathophysiology affecting the client and extent of feelings of hopelessness, helplessness, and loss of control over life; level of anxiety; and perception of situation.

Indicators of degree of disequilibrium and need for intervention to prevent or resolve the crisis. Studies suggest that 20% to 40% of physically ill individuals are depressed (Robinson, 2002). Impairment of normal functioning for more than 2 weeks, especially in presence of chronic condition, may reflect depression, requiring further evaluation. Note: In contrast, depression is believed to contribute to the development and progression of some physical illnesses, such as heart or vascular disease or certain viral infections (Thomas, 2010).

Establish therapeutic nurse-client relationship.

Client may feel less inhibited in the context of this relationship to verbalize feelings of helplessness and powerlessness and feel more freedom to discuss changes that may be necessary in the client's life to improve situation.

(continues on page 838)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Assess presence of positive coping skills and inner strengths, such as use of relaxation techniques, willingness to express feelings, and use of support systems.	When the individual has coping skills that have been successful in the past, they may be used in the current situation to relieve tension and preserve the individual's sense of control. However, limitations of condition may impact choices available to client; for example, playing a musical instrument to relieve stress may not be possible for individual with tremors or hemiparesis, but listening to tapes or CDs may provide some degree of comfort.
Encourage client to talk about what is happening at this time and what has occurred to precipitate feelings of helplessness and anxiety.	Provides clues to assist client to develop coping and regain equilibrium.
Provide quiet, nonstimulating environment. Determine what client needs, and provide, if possible. Give simple, factual information about what client can expect and repeat as necessary.	Decreases anxiety and provides control for the client during crisis situation.
Allow client to be dependent in the beginning, with gradual resumption of independence in ADLs, self-care, and other activities. Make opportunities for client to make simple decisions about care and other activities when possible, accepting choice not to do so.	Promotes feelings of security—client knows nurse will provide safety. As control is regained, client has the opportunity to develop adaptive coping and problem-solving skills.
Accept verbal expressions of anger, setting limits on maladaptive behavior.	Verbalizing angry feelings is an important process for resolution of grief and loss. However, preventing destructive actions, such as striking out at others, preserves client's self-esteem.
Discuss feelings of self-blame or projection of blame on others.	Although these mechanisms may be protective at the moment of crisis, they eventually are counterproductive and intensify feelings of helplessness and hopelessness.
Note expressions of inability to find meaning in life or reason for living and feelings of futility or alienation from God.	Crisis situation may evoke questioning of spiritual beliefs, affecting ability to cope with current situation and plan for the future.
Promote safe and hopeful environment, as needed. Identify positive aspects of this experience and assist client to view it as a learning opportunity.	May be helpful while client regains inner control. The ability to learn from the current situation can provide skills for moving forward.
Provide for gradual implementation and continuation of necessary behaviors or lifestyle changes. Reinforce positive adaptation and new coping behaviors.	Reduces anxiety of sudden change and allows for developing new and creative solutions.

#### **Collaborative**

Refer to other resources as necessary, such as clergy, psychiatric clinical nurse specialist, psychiatrist, family or marital therapist, and addiction support groups.

Additional assistance may be needed to help client resolve problems or make decisions. Note: If untreated, depression may complicate recovery from physical illness (Robinson, 2002).

## **NURSING DIAGNOSIS: Decisional Conflict**

### **May Be Related To**

Conflicting information sources  
Inexperience with or interference in decision-making  
Insufficient information  
Conflict with moral obligations

### **Possibly Evidenced By**

Questioning of moral principle while attempting a decision  
Recognizes undesired consequences of alternative actions being considered  
Delay in decision making; vacillation among choices  
Physical signs of tension; self-focused

**NURSING DIAGNOSIS:** **Decisional Conflict** (continued)**Desired Outcomes/Evaluation Criteria: Client Will****Decision-Making NOC**

Verbalize awareness of problem-solving abilities.

Use relevant information, and cultural/social considerations as appropriate, to make decisions.

Identify alternatives and potential consequences.

Verbalize satisfaction with decisions made.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Decision-Making Support</b> <b>NIC</b>	
<i>Independent</i>	
Establish therapeutic nurse-client relationship.	Client may feel less inhibited in the context of this relationship to verbalize feelings of helplessness and powerlessness and feel more freedom to discuss changes that may be necessary in the client's life to improve situation.
Note expressions of indecision, dependence on others, and inability to manage own activities of daily living (ADLs).	May indicate need to lean on others for a time. Early recognition and intervention can help client regain equilibrium.
Evaluate ability to understand events. Correct misperceptions and provide factual information.	Assists in identification and correction of perception of reality and enables problem-solving to begin.
Active-listen; identify reason for indecisiveness.	Helps client to clarify problem and begin looking for resolution, alternative choices.
Identify cultural values and beliefs or moral obligations that may be creating conflict for client.	These issues must be addressed before client can be at peace with the decision that is made.
Provide support for client to problem-solve solutions for current situation. Provide information and reinforce reality as client begins to ask questions and look at what is happening.	Helping client and SO to brainstorm possible solutions and giving consideration to the pros and cons of each promotes feelings of self-control and strengthens self-esteem.
<i>Collaborative</i>	
Refer to other resources as necessary, such as clergy, psychiatric clinical nurse specialist, psychiatrist, family or marital therapist, and addiction support groups.	Additional assistance may be needed to help client resolve problems or make decisions. Note: If untreated, depression may complicate recovery from physical illness (Robinson, 2002).

**NURSING DIAGNOSIS:** **compromised family Coping****May Be Related To**

Family disorganization or role change

Exhaustion of support person's capacity

Insufficient reciprocal support

Insufficient understanding of information by support person

**Possibly Evidenced By**

Client complaint about support person's response to health problem

Support person reports inadequate knowledge or understanding that interferes with effective behaviors

Assistive behaviors by support person produce unsatisfactory results

Protective behavior by support person incongruent with client's abilities

Support person withdraws from client

**Desired Outcomes/Evaluation Criteria—Family Will****Family Coping NOC**

Identify resources within themselves to deal with situation.

Visit regularly and participate positively in care of client, within limits of abilities.

Express more realistic understanding and expectations of the client.

Provide opportunity for client to deal with situation in own way.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Family Involvement Promotion NIC</b>	
<b>Independent</b>	
Establish rapport and acknowledge difficulty of the situation for the family.	May assist family to accept what is happening and be willing to share problems with caregivers.
Determine current knowledge and perception of the situation.	Lack of information or unrealistic perceptions can interfere with family members' and client's response to illness situation.
Assess level of anxiety present in family and SO.	Anxiety level needs to be dealt with before problem-solving can begin. Individuals may be so preoccupied with own reactions to situation that they are unable to respond to another's needs.
Evaluate preillness and current behaviors that are interfering with care or recovery of the client.	Information about family problems, such as divorce or separation, financial limitations, and substance use, will be helpful in determining options and developing an appropriate plan of care.
Discuss underlying reasons for client behaviors with family.	When family members know why client is behaving in different ways, it helps them understand and accept or deal with situation.
Assist family/client to understand "who owns the problem" and who is responsible for resolution. Avoid placing blame or guilt (Gordon, 2000).	When these boundaries are defined, each individual can begin to take care of own self and stop taking care of others in inappropriate ways.
Reframe negative expressions into positives whenever possible.	Promotes more hopeful attitude and helps family and client look toward the future.
Involve SO in information giving, problem-solving, and care of client as feasible. Identify other ways of demonstrating support while maintaining client's independence.	Information can reduce feelings of helplessness. Involvement in care enhances feelings of control and self-worth.
<b>Collaborative</b>	
Refer to appropriate resources for assistance, as indicated, such as counseling, psychotherapy, and financial and spiritual support.	May need additional assistance in resolving family issues.

### NURSING DIAGNOSIS: **readiness for enhanced family Coping**

#### Possibly Evidenced By

- Expresses desire to enhance connection with others who have experienced a similar situation
- Expresses desire to choose experiences that optimize wellness
- Expresses desire to acknowledge growth impact of crisis
- Expresses desire to enhance health promotion, enrichment of lifestyle

#### Desired Outcomes/Evaluation Criteria—Family Will

#### Family Resiliency NOC

- Express willingness to look at own role in family's growth.
- Use community resources for support or assistance as needed.
- Undertake tasks leading to change.
- Verbalize feelings of self-confidence and satisfaction with progress being made.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Family Support NIC</b>	
<b>Independent</b>	
Provide opportunities for family to talk with client and/or caregiver(s).	Reduces anxiety and allows expression of what has been learned and how they are managing as well as opportunity to make plans for the future and share support.
Listen to family's expressions of hope, planning, effect on relationships and life, and change of values.	Provides clues to avenues to explore for assistance with growth.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Provide opportunities for, and instruction in, how SOs can care for client. Discuss ways in which they can support client in meeting own needs.	Enhances feelings of control and involvement in situation in which SOs cannot do many things. Also provides opportunity to learn how to be most helpful when client is discharged from care.
Provide a role model with which family may identify.	Having a positive example can help with adoption of new behaviors to promote growth.
Discuss importance of open communication. Role-play effective communication skills of active-listening, "I-messages," and problem-solving.	Helps individuals to express needs and wants in ways that will develop family cohesiveness. Promotes solutions in which everyone wins.
Encourage family to learn new and effective ways of dealing with feelings.	Effective recognition and expression of feelings clarify situation for involved individuals.
Encourage seeking support appropriately. Give information about available persons and agencies.	Permission to seek help as needed allows them to choose to take advantage of available assistance and resources.
<b>Collaborative</b> Refer to specific support group(s) as indicated.	Provides opportunities for sharing experiences, provides mutual support and practical problem-solving, and can aid in decreasing alienation and helplessness.

### NURSING DIAGNOSIS: Anxiety [specify level]

#### May Be Related To

Major change in health status, economic status, or role function  
 Maturational/situational crisis; stressors  
 Family history of anxiety  
 Interpersonal contagion/transmission  
 Conflict about life goals

#### Possibly Evidenced By

Worried about change in life event  
 Apprehensive; distressed  
 Dry mouth  
 Alteration in sleep pattern  
 Increased tension  
 Self-focused  
 Change in blood pressure, pulse, and/or respirations  
 Facial tension; hand tremors; voice quivering  
 Blocking of thoughts; rumination; confusion  
 Diminished ability to problem solve

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Anxiety Self-Control NOC

Acknowledge and discuss fears and concerns.  
 Verbalize awareness of feelings of anxiety and healthy ways to deal with them.  
 Demonstrate problem-solving and use resources effectively.

##### Anxiety Level NOC

Appear relaxed and report anxiety is reduced to a manageable level.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Anxiety Reduction NIC</b> <i>Independent</i> Note palpitations and elevated pulse or respiratory rate.	Changes in vital signs may suggest the degree of anxiety the client is experiencing or reflect the impact of physiological factors such as pain or endocrine imbalances.
Acknowledge presence of anxiety. Validate observations with client, for example, "You seem to be afraid."	Feelings are real, and it is helpful to bring them out in the open so they can be discussed and dealt with.

(continues on page 842)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Assess degree and reality of threat to client and level of anxiety—mild, moderate, severe—by observing behavior, such as clenched hands, wide eyes, startle response, furrowed brow, clinging to family and staff, or physical and verbal lashing out.	Individual responses can vary according to cultural beliefs and traditions and culturally learned patterns. Distorted perceptions of the situation may magnify feelings.
Note narrowed focus of attention and client concentrating on one thing at a time.	Narrowed focus usually reflects extreme fear or panic.
Observe speech content, vocabulary, and communication patterns, such as rapid or slow, pressured speech; words commonly used, repetition, use of humor or laughter, and swearing.	Provides clues about such factors as the level of anxiety, ability to comprehend what is currently happening, cognition difficulties, and possible language differences.
Assess severity of pain when present. Delay gathering of information if pain is severe.	Severe pain and anxiety leave little energy for critical thinking and other activities.
Determine client's and SO's perception(s) of the situation.	Regardless of the reality of the situation, perception affects how each individual deals with the illness and stress.
Acknowledge reality of the situation as the client sees it, without challenging the belief.	Client may need to deny reality until ready to deal with it. It is not helpful to force the client to face facts.
Evaluate coping and defense mechanisms being used to deal with the perceived or real threat.	May be dealing well with the situation at the moment; for example, denial and regression may be helpful coping mechanisms for a time. However, use of such mechanisms diverts energy the client needs for healing, and problems need to be dealt with at some point in time.
Review coping mechanisms used in the past, such as problem-solving skills and recognizing and asking for help.	Provides opportunity to build on resources the client and SO may have used successfully.
Assist client to use the energy of anxiety for coping with the situation when possible.	Moderate anxiety heightens awareness and can help motivate the client to focus on dealing with problems.
Maintain frequent contact with the client and SO. Be available for listening and talking, as needed.	Establishes rapport, promotes expression of feelings, and helps client and SO look at realities of the illness and treatment without confronting issues they are not ready to deal with.
Acknowledge feelings, as expressed, using active-listening or reflection. If actions are unacceptable, take necessary steps to control or deal with behavior. (Refer to ND: risk for Violence.)	Often acknowledging feelings enables client to deal more appropriately with situation. May need chemical or physical control for brief periods.
Identify ways in which client can get help when needed, including telephone numbers of contact persons.	Provides assurance that staff and resources are available for assistance/support.
Stay with or arrange to have someone stay with client, as indicated.	Continuous support may help client regain internal locus of control and reduce anxiety and fear to a manageable level.
Provide accurate information as appropriate and when requested by the client and SO. Answer questions freely and honestly and in language that is understandable by all. Repeat information as necessary; correct misconceptions.	Complex and/or anxiety-provoking information can be given in manageable amounts over an extended period. As opportunities arise and facts are given, individuals will accept what they are ready for. Note: Words and phrases may have different meanings for each individual; therefore, clarification is necessary to ensure understanding.
Avoid empty reassurances, with statements of “everything will be all right.” Instead, provide specific information, such as “Your heart rate is regular, your pain is being easily controlled, and that is what we want,” or “Your CD4 count has been stable for the last three visits.”	It is not possible for the nurse to know how the specific situation will be resolved, and false reassurances may be interpreted as lack of understanding or honesty, further isolating the client. Sharing observations used in assessing condition and prognosis provides opportunity for client and SO to feel reassured.
Note expressions of concern or anger about treatment or staff.	Anxiety about self and outcome may be masked by comments or angry outbursts directed at therapy or caregivers.
Ask client and SO to identify what he or she can or cannot do about what is happening.	Assists in identifying areas in which control can be exercised and those in which control is not possible.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Provide as much order and predictability as possible in scheduling care, activities, and visitors.	Helps client anticipate and prepare for difficult treatments or movements, as well as look forward to pleasant occurrences.
Instruct in ways to use positive self-talk: “I can manage this pain for now,” or “My cancer is shrinking.”	Internal dialogue is often negative. When this is shared out loud, the client becomes aware and can be directed in the use of positive self-talk, which can help reduce anxiety.
Encourage client to develop regular exercise and activity program.	Has been shown to raise endorphin levels to enhance sense of well-being and help reduce level of anxiety.
Encourage and instruct in guided imagery or other relaxation methods, such as imagining a pleasant place, use of music, deep breathing, meditation, and mindfulness (Healthwise Staff, 2011).	Promotes release of endorphins and aids in developing internal locus of control, reducing anxiety. May enhance coping skills, allowing body to go about its work of healing.
<b>Collaborative</b>	
Provide touch, Therapeutic Touch, massage, and other adjunctive therapies as indicated (Krieger, 1998).	Aids in meeting basic human need, decreasing sense of isolation and assisting client to feel less anxious. Note: Therapeutic Touch requires the nurse to have specific knowledge and experience to use the hands to correct energy field disturbances by redirecting human energies to help or heal.
<b>Collaborative</b>	
Administer medications, as needed, for example:	
Antianxiety agents, such as diazepam (Valium), clorazepate (Tranxene), or chlordiazepoxide (Librium)	Antianxiety agents and/or antidepressants may be useful for brief periods to assist the client and SO to reduce anxiety to manageable levels, providing opportunity for initiation of client's own coping skills. Note: Use of SSRIs, such as Prozac or Zoloft, has been associated with sexual function complaints. Alternatives may need to be considered. Also, ethnic variations affecting psychotropic drugs require close monitoring to determine therapeutic dosage. For example, East Asians and blacks may be more sensitive or react faster, have higher plasma drug levels, and have increased risk of side effects, necessitating lower dosage than whites in general (Munoz & Hilgenberg, 2005).
Benzodiazepines, such as alprazolam (Xanax), oxazepam (Serax), lorazepam (Ativan), or temazepam (Restoril)	
Selective serotonin reuptake inhibitors (SSRIs), such as fluoxetine (Prozac), sertraline (Zoloft), fluvoxamine (Luvox), citalopram HABr (Celexa), or paroxetine HCL (Paxil)	
Other drugs, such as buspirone (BuSpar) or doxepin (Adapin, Sinequan)	

### NURSING DIAGNOSIS: risk for situational low Self-Esteem

#### Possibly Evidenced By

Decrease in control over environment  
Physical illness; functional impairment; alteration in body image  
History of abandonment, neglect  
Pattern of helplessness  
Unrealistic self-expectations

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Self-Esteem NOC

Verbalize realistic view and acceptance of self in situation.  
Identify existing strengths and view self as capable person.  
Recognize and incorporate change into self-concept in accurate manner without negating self-worth.  
Demonstrate adaptation to changes or events that have occurred as evidenced by setting of realistic goals and active participation in work, play, and personal relationships.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Self-Esteem Enhancement NIC</b>	
<b>Independent</b>	
Ask how the client would like to be addressed.	Shows courtesy and respect and acknowledges person.
Identify SO from whom the client derives comfort and who should be notified in case of emergency.	Allows provisions to be made for specific person(s) to visit or remain close and provides needed support for client. Note: May or may not be legal next of kin.
Identify basic sense of self-esteem and image client has of existential, physical, psychological self. Identify locus of control.	May provide insight into whether this is a single episode or recurrent or chronic situation and can help determine needs and treatment plan. Determining whether the individual's locus of control is internal or external facilitates choosing most effective interventions.
Determine client's perception of threat to self.	Client's perception is more important than what is really happening and needs to be dealt with before reality can be addressed.
Active-listen to client concerns and fears.	Conveys sense of caring and can be helpful in identifying the client's needs, problems, and coping strategies and how effective they are. Provides opportunity to develop and begin a problem-solving process.
Encourage verbalization of feelings, accepting what is said.	Helps client and SO begin to adapt to change and reduces anxiety about altered function or lifestyle.
Discuss stages of grief and the importance of grief work. (Refer to ND: Grieving.)	Grieving is a necessary step for integration of change or loss into self-concept.
Provide nonthreatening environment; listen and accept client as presented.	Promotes feelings of safety, encouraging verbalization.
Observe nonverbal communication, including body posture and movements, eye contact, gestures, and use of touch.	Nonverbal language is a large portion of communication and therefore is extremely important. How the person uses touch provides information about how it is accepted and how comfortable the individual is with being touched.
Reflect back to the client what has been said, for example, "You were upset when he told you that."	Clarification and verification of what has been heard promotes understanding and allows client to validate information; otherwise, assumptions may be inaccurate.
Observe and describe behavior in objective terms.	All behavior has meaning, some of which is obvious and some of which needs to be identified. This is a process of educated guesswork and requires validation by the client.
Identify age and developmental level.	Age is an indicator of the stage of life client is experiencing, whether it be adolescence or middle age. However, developmental level may be more important than chronological age in anticipating and identifying some of the client's needs. Some degree of regression occurs during illness, depending on many factors, such as the normal coping skills of the individual, the severity of the illness, and family and cultural expectations.
Discuss client's view of body image and how illness or condition might affect it.	The client's perception of a change in body image may occur suddenly or over time, such as actual loss of a body part through injury or surgery, or a perceived loss, such as a heart attack; or be a continuous subtle process, such as chronic illness, eating disorders, or aging. Awareness can alert the nurse to the need for appropriate interventions tailored to the individual need.
Encourage discussion of physical changes in a simple, direct, and factual manner. Give realistic feedback and discuss future options such as rehabilitation services.	Provides opportunity to begin incorporating actual changes in an accepting and hopeful atmosphere.
Acknowledge efforts at problem-solving, resolution of current situation, and future planning.	Provides encouragement and reinforces continuation of desired behaviors.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Recognize client's pace for adaptation to demands of current situation.	Failure to acknowledge client's need to take time and/or pressuring client to "get on with it" conveys a lack of acceptance of the person as an individual and may result in feelings of lowered self-esteem.
Introduce tasks at client's level of functioning, progressing to more complex activities as tolerated.	Provides opportunity for client to experience successes, reaffirming capabilities and enhancing self-worth.
Ascertain how the client sees own role within the family system: breadwinner, homemaker, or husband or wife.	Illness may create a temporary or permanent problem in role expectations. Sexual role and how the client views self in relation to the current illness also play important parts in recovery.
Assist client and SO with clarifying expected roles and those that may need to be relinquished or altered.	Provides opportunity to identify misconceptions and begin to look at options; promotes reality orientation.
Determine client awareness of own responsibility for dealing with situation and personal growth.	Conveys confidence in client's ability to cope. When client acknowledges own part in planning and carrying out treatment plan, he or she has more investment in following through on decisions that have been made.
Assess impact of condition, surgery, or medication regimen on sexuality.	Sexuality encompasses the whole person in the total environment. Many times, problems of illness are superimposed on already existing problems of sexuality and can affect client's sense of self-worth. Some problems are more obvious than others, such as illness involving the reproductive parts of the body. Others are less obvious, such as sexual values and role in family: mother, wage earner, or single parent.
Be alert to comments and innuendos, which may mean the client has a concern in the area of sexuality.	People are often reluctant and/or embarrassed to ask direct questions about sexual or sexuality concerns.
Be aware of caregiver's feelings about dealing with the subject of sexuality.	Nurses and caregivers are often as reluctant and embarrassed in dealing with sexuality issues as most clients. (Refer to CP: Extended/Long-Term Care; ND: Sexual Dysfunction.)
<b>Collaborative</b>	
Provide information and referral to community resources.	Enables client and SO to be in contact with interested groups with access to assistive and supportive devices, services, and counseling.
Support participation in group or community activities, such as assertiveness classes, volunteer work, and support groups.	Promotes skills of coping and sense of self-worth. Provides role models and facilitates problem-solving.
Refer to psychiatric support or therapy group and social services, as indicated.	May be needed to assist client and SO to achieve optimal recovery.
Refer to appropriate resources for sexuality counseling as need indicates.	May be someone with comfort level and knowledge who is available, or it may be necessary to refer to professional resources for additional guidance and support.

## NURSING DIAGNOSIS: Grieving

### May Be Related To

Anticipatory or actual loss of significant object (e.g., parts or processes of body, status, job, home)  
Anticipatory loss of a significant other  
Death of a significant other  
Lack of social support

### Possibly Evidenced By

Alteration in activity level, sleep pattern, dream patterns  
Anger; blaming; despair  
Finding meaning in a loss  
Detachment  
Disorganization  
Psychological distress, panic behavior

(continues on page 846)

**NURSING DIAGNOSIS:** **Grieving** (continued)**Desired Outcomes/Evaluation Criteria—Client Will****Grief Resolution NOC**

Identify and express feelings freely and effectively.  
Verbalize a sense of progress toward acceptance of loss.  
Function at an acceptable level and participate in work and ADLs, as appropriate.

**ACTIONS/INTERVENTIONS****RATIONALE****Grief Work Facilitation NIC****Independent**

Provide open environment in which client feels free to realistically discuss feelings and concerns.

Therapeutic communication skills, such as active-listening, silence, being available, and acceptance, provide opportunity and encourage the client to talk freely and deal with the perceived or actual loss (Evesham, 2017).

Determine client perception and meaning of loss—current and past. Note cultural or religious factors and expectations.

Affects client's responses and needs to be acknowledged in planning care.

Identify stage of grieving and effect on functioning:

Awareness allows for appropriate choice of interventions because individuals handle grief in many different ways.

**Denial:** Be aware of avoidance behaviors, such as anger and/or withdrawal; allow client to talk about what he or she chooses, and do not try to force client to “face the facts.”

Denying the reality of diagnosis and/or prognosis is an important phase in which the client protects self from the pain and reality of the threat of loss. Each person does this in an individual manner based on previous experiences with loss and cultural or religious factors.

**Anger:** Note behaviors of withdrawal, lack of cooperation, and direct expression of anger; be alert to body language and check meaning with client, noting congruency with verbalizations; encourage, and provide opportunity for, verbalization of anger; and acknowledge feelings and set limits regarding destructive behavior.

Denial gives way to feelings of anger, rage, guilt, and resentment. Client may find it difficult to express anger directly and may feel guilty about normal feelings of anger. Although staff may have difficulty dealing with angry behaviors, acceptance allows client to work through the anger and move on to more effective coping behaviors.

**Bargaining:** Be aware of statements such as “... if God will just . . . I will do . . .” Allow verbalization without confrontation about realities.

Bargaining with care providers or God often occurs and may be helpful in beginning resolution and acceptance. Client may be working through feelings of guilt about things done or undone.

**Depression:** Give client permission to be where he or she is, provide hope within parameters of individual situation without giving false reassurance, and provide comfort and availability as well as caring for physical needs.

When client can no longer deny the reality of the loss, feelings of helplessness and hopelessness replace feelings of anger. The client needs information that this is a normal progression of feelings.

**Acceptance:** Respect client's needs and wishes for quiet, privacy, and/or talking.

Having worked through the denial, anger, and depression stages, client often prefers to be alone and may not want to talk much at this point. Client may still cling to hope, which can be sustaining through whatever is currently happening.

Active-listen to client's concerns and be available for support, as necessary.

The process of grieving does not proceed in an orderly fashion but fluctuates with various aspects of all stages present at one time or another. If process is dysfunctional or prolonged, more aggressive interventions may be required to facilitate the process.

Determine quality of interactions with others, including family members.

Although periods of withdrawal and loneliness usually accompany grieving, persistent isolation may indicate deepening depression, necessitating further evaluation and intervention. Note: Family/SO may not be dysfunctional but may be intolerant of client's behaviors.

Identify and problem-solve solutions to existing physical responses, such as eating, sleeping, activity levels, and sexual desire.

May need additional assistance to deal with the physical aspects of grieving.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Assess needs of SO and assist, as indicated.	Identification of problems indicating dysfunctional grieving allows for individual interventions.
Include family/SO, as appropriate, when determining future needs.	Depending on client's desires and legal requirements, choices regarding future plans (e.g., living situation, continuation of care, end-of-life decisions, funeral arrangements) can provide guidance and peace of mind.
Discuss healthy ways of dealing with difficult situation.	Provides opportunity to look toward the future and plan for family's/SO's needs (e.g., for life after loss).
<b>Collaborative</b> Refer to other resources, such as support groups, counseling, spiritual or pastoral care, and psychotherapy, as indicated.	May need additional help to resolve grief, make plans, and look toward the future.

## NURSING DIAGNOSIS: risk for impaired Religiosity

### Possibly Evidenced By

Illness; depression; suffering  
Life transitions  
Cultural/environmental barriers to practicing religion  
Ineffective support; social isolation

### Desired Outcomes/Evaluation Criteria—Client Will

#### Spiritual Health NOC

Participate in beliefs and rituals of desired religion.  
Discuss beliefs and values about spiritual or religious issues.  
Attend religious or worship services of choice as desired.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Spiritual Support NIC</b>	
<b>Independent</b>	
Listen to client's and SO's reports and expressions of anger and concern or alienation from God. Note sense of guilt or retribution.	May be suffering from severe or terminal illness or accident, straining resources and affecting client's ability to cope. Perception of guilt may cause spiritual crisis or suffering, resulting in rejection of religious activities and symbols.
Discuss differences between grief and guilt and help client to identify and deal with each. Point out consequences of actions based on guilt.	As client recognizes consequences of actions, they can be discussed, and desire to change may enhance new coping skills, avoid acting out of false guilt, and enable client to resume desired religious activities.
Use therapeutic communication skills of reflection and active-listening.	Communicates acceptance and enables client to find own solutions to concerns.
Determine sense of futility, feelings of hopelessness, and lack of motivation to help self.	Indicators that client may see no, or only limited, options or personal choices available and lack energy to deal with situation.
Assess extent of depression client may be experiencing.	Some studies suggest that a focus on religion may protect against depression (Columbia University, 2014).
Note recent changes in behavior, such as withdrawal from others and religious activities and dependence on alcohol or medications.	Helpful in determining severity and duration of situation and possible need for additional referrals, such as substance withdrawal. Lack of connectedness with self or others impairs ability to trust others or feel worthy of trust from others or God.
Suggest use of journaling and/or reminiscence.	Promotes life review. Can assist in clarifying values and ideas, recognizing and resolving feelings and situation, and identifying reasons for resuming desired religious activities.

(continues on page 848)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Encourage client to identify SO(s) and others such as spiritual advisor or parish nurse who can provide needed support.	Ongoing support is required to enhance sense of connectedness and strengthen religious ties as desired.
<b>Religious Ritual Enhancement NIC</b>	
Identify client's religious affiliation, associated rituals, and beliefs.	Helps determine individual's needs and possible resources, if desired.
Make time for nonjudgmental discussion of philosophical issues related to religious belief patterns and customs.	Open communication can assist client to check reality of perceptions and identify personal options and willingness to resume desired activities.
Discuss desire to continue or reconnect with previous belief patterns and customs.	Enables client to identify barriers to participating in desired activities and take appropriate actions to resume them.
Involve client in refining healthcare goals and therapeutic regimen, as appropriate.	Identifies role illness is playing in current concerns about ability to or appropriateness of participating in desired religious activities.
Provide privacy for meditation, prayer, or performance of rituals, as appropriate.	Allows client to engage in spiritual activities in own way without fear of interruption or judgment of others.
Explore alternatives to, or modifications for, ritual based on setting and individual needs or limitations.	Assists client to develop new ways of expressing religious beliefs and satisfying these needs.
<b>Collaborative</b>	
Refer to spiritual resources, such as spiritual advisor—who has qualifications and experience in dealing with specific problems individual is concerned about—or to facility's chaplain or visiting clergy and parish nurse.	Provides answers to spiritual questions, assists in the journey of self-discovery, helps client learn to accept, forgive self, and engage in desired rituals.

## NURSING DIAGNOSIS: **ineffective Health Management**

### May Be Related To

Complexity of therapeutic regimen; decisional conflicts  
Economic difficulties  
Perceived barrier/benefit  
Family conflict, patterns of health care; insufficient social support

### Possibly Evidenced By

Difficulty with prescribed regimens  
Failure to include treatment regimen in daily living  
Ineffective choices in daily living for meeting health goals  
Failure to take action to reduce risk factors

### Desired Outcomes/Evaluation Criteria—Client Will

#### **Self-Management: Acute Illness [or] Chronic Disease NOC**

Participate in the development of goals and treatment plan.  
Verbalize accurate knowledge of disease, prognosis, and potential complications.  
Demonstrate behaviors or changes in lifestyle necessary to incorporate or maintain therapeutic regimen in daily life.  
Identify and use available resources.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Values Clarification NIC</b>	
<i>Independent</i>	
Review client's and SO's knowledge and understanding of the need for treatment or medication as well as consequences of actions and choices. Note ability to comprehend information, including literacy, level of education, and primary language.	Provides opportunities to clarify viewpoints or misconceptions. Verifies that client and SO have accurate and factual information with which to make informed choices.
Be aware of developmental and chronological age.	Impacts ability to understand own needs and incorporate into treatment regimen.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Determine cultural, spiritual, and health beliefs and ethical concerns.	Provides insight into thoughts and factors related to individual situation. Beliefs will affect client's perception of situation and participation in treatment regimen. Treatment may be incongruent with client's social and cultural lifestyle and perceived role/responsibilities.
<b>Self-Modification Assistance NIC</b>	
Review treatment plan with client and SO.	Provides opportunities to exchange accurate information and to clarify viewpoints or misconceptions.
Contract with client for participation in care.	Client who agrees to own responsibility is more apt to adhere to treatment plan.
Establish graduated goals or modified regimen as necessary; work out alternate solutions.	Promotes client involvement and independence; provides opportunity for compromise and may enhance cooperation with regimen. When client participates in setting goals, there is a sense of investment that encourages cooperation and willingness to follow through with the program.
Assess availability and use of support systems. Identify additional resources, as appropriate.	Access to and proper use of helpful resources can assist client in meeting treatment goals and provide purpose for living. Presence of caring, empathic family/SO(s) can help client in process of recovery.
Determine problems that may, or do, interfere with treatment, including lack of financial or personal resources or lack of availability of providers. Assess level of anxiety, locus of control, and sense of powerlessness.	Many factors may be involved in behavior that is disruptive to the treatment regimen, such as fear of hospitalization or treatment, denial of situation consequences, suspicion about healthcare system, and physical factors such as pain, hypoxemia, and chemical imbalance.
Note length of illness and prognosis.	Clients tend to become passive and dependent in long-term, debilitating illness.
Active-listen client's reports and comments	Conveys message of concern and belief in individual's capabilities to resolve situation in positive manner.
Develop a system for self-monitoring. Share data pertinent to client's condition such as laboratory results or blood pressure (BP) readings.	Provides a sense of control; enables client to follow own progress and make informed choices.
Have same personnel care for client as much as possible.	Enables relationship to develop in which the client can begin to trust and participate in care and may be willing to give up smoking or other negative behaviors.
Accept client's choice or point of view even if it appears to be self-destructive, such as a decision to continue smoking.	Client has the right to make own decisions, and acceptance may give a sense of control, which can help client look more clearly at consequences. Confrontation is not beneficial and may actually be detrimental to future cooperation and goal achievement. Negative feelings regarding these choices may create power struggles and be expressed in judgmental behaviors that block or interfere with client's wishes, comfort, and/or care. Note: If resolution cannot be found, providers have the right to terminate their services with appropriate notice.
Be aware of own and caregiver's response to client's treatment choices such as refusal of blood or chemotherapy and living will or advance directive choices.	

### NURSING DIAGNOSIS: risk for self- or other-directed Violence

#### Possibly Evidenced By

Physical health issue; neurological impairment; alteration in cognitive functioning  
 Mental health issue (e.g., depression)  
 Employment concern; insufficient personal resources  
 Impulsivity; history of violence; suicidal behavior

(continues on page 850)

**NURSING DIAGNOSIS:** risk for self- or other-directed Violence**Desired Outcomes/Evaluation Criteria—Client Will****Impulse Self-Control NOC**

Acknowledge realities of the situation.

Verbalize understanding of reason(s) for behavior/precipitating factors.

Reports absence of thoughts of violence or suicidal ideation.

**Agitation Level NOC**

Demonstrate self-control, as evidenced by relaxed posture and nonviolent behavior.

**ACTIONS/INTERVENTIONS****RATIONALE****Mood Management NIC****Independent**

Observe for early signs of distress and investigate possible causes.

Irritability, pacing, shouting or cursing, lack of cooperation, and demanding behavior may all be signs of increasing anxiety or indicate change in health status of confused client that requires further evaluation.

Identify conditions that may interfere with ability to control own behavior.

Acute or chronic brain syndrome, drug-induced or post-surgical confusion may precipitate violent behavior that is difficult to control.

Assume that the client has control and is responsible for own behavior.

Often enables the individual to exercise control. Note: When violent behavior is the result of drug use, client may not be able to respond appropriately.

Remain calm and state limits on behavior in a firm manner. Be truthful and nonjudgmental.

Understanding that helplessness and fear underlie this behavior aids in choosing appropriate response.

Accept client's anger without reacting on an emotional basis.

Responding with anger is not helpful in resolving the situation and may result in escalating client's behavior. Anger is usually not directed at the nurse but at the situation and feelings of powerlessness.

Maintain straightforward communication and assist client to learn assertive rather than manipulative, nonassertive, or aggressive behavior.

Avoids reinforcing manipulative behavior and enhances positive interactions with others, accomplishing the goal of getting needs met in acceptable ways.

Help client identify more adequate solutions and behaviors such as motor activities or exercise. Redirect and provide directions for actions client can take.

Promotes release of energies in acceptable ways. Redirecting confused client can minimize escalation of agitation. (Refer to CP: Dementia of the Alzheimer's Type/Vascular Dementia.)

Give as much autonomy as is possible in the situation.

Enhances feelings of power and control in a situation in which many things are not within individual's control.

Monitor for suicidal or homicidal ideation, for example, morbid or anxious feelings while with the client; thoughts expressed by, or warning from, the client, "It doesn't matter, I'd be better off dead"; mood swings, putting affairs in order, and previous suicide attempt.

Indicators of need for further assessment and intervention or psychiatric care.

Assess suicidal intent (scale of 1 to 10) by asking directly if client is thinking of killing self, has plan, means, and so on.

Provides guidelines for necessity and urgency of interventions. Direct questioning is most helpful when done in a caring, concerned manner.

Acknowledge reality of suicide or homicide as an option. Discuss consequences of actions if client were to follow through on intent. Ask how it will help client resolve problems.

Client may focus on suicide, or possibly homicide, as the "only" option, and this response provides an opening to look at and discuss other options. Note: Be aware of own responsibility under Tarasoff's rule to warn possible victim(s) when client is expressing homicidal ideation. (Under Tarasoff's rule, the counselor/care provider has a legal responsibility to notify a third party of a credible threat made by the client.) (Tarasoff v. Regents of the University of California—17 Cal.3d 425 [1976]).

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<b>Environmental Management: Violence Prevention NIC</b> Provide protection within the environment such as constant observation and removal of objects that might be used to harm self and others.	May need more structure to maintain control until own internal locus of control is regained.
Tell client to stop.	May be sufficient to help client control own actions if exhibiting hostile actions. Note: Client is often afraid of own actions and wants staff to set limits.
Use an organized team approach when necessary to subdue client with force. Tell client clearly and concisely what is happening.	Knowing and practicing these actions before they are needed helps prevent untoward problems. Keeping client informed can help client to regain internal control.
Hold client; place in restraints or seclusion if necessary. Do so in a calm, positive, nonstimulating, and nonpunitive manner.	As a last resort, physical restraint may be necessary while the client regains control. Note: These measures are meant to protect client, not punish the behavior.
Apply and adjust restraint devices properly.	It is important to maintain body alignment and client safety and comfort.
Document precise reason for restraints, actions taken, and doctor's order. Check restraints frequently per facility protocol, each time documenting the condition and how long the restraints are used.	Restraints are to be used for very specific reasons, which need to be clearly documented to avoid overuse or misuse and to ensure client safety.
<b>Collaborative</b> Administer medications, such as antianxiety or antipsychotic agents, sedatives, and narcotics, as appropriate.	May be indicated to quiet or control behavior. Note: May need to be withheld if they are suspected to be the cause of, or contribute to, the behavior.
Refer to psychiatric resource(s): psychiatric clinical nurse specialist, psychiatrist, psychologist, social worker.	More in-depth assistance may be needed to deal with client and defuse situation. Learning new ways to deal with feelings can provide opportunity for individual to manage life in a more optimal way.
Encourage participation in classes such as anger management. Discuss what client is learning about dealing with anger.	Attending class helps individual to learn positive ways to handle anger instead of usual acting out.

## DEMENTIAS—ALZHEIMER'S TYPE/VASCULAR DEMENTIA/LEWY BODY DISEASE/FRONTOTEMPORAL DEMENTIA

### I. Pathophysiology (Alzheimer's Association, 2017; Nelson-Marsh, 2005)

- a. Cognitive disorder characterized by impaired memory, language, thinking, and perception
- b. Alzheimer's, vascular, and Lewy body dementias are irreversible and share common symptomology and therapeutic intervention.
- c. Criteria for dementia diagnosis
  - i. Decline in memory and at least one of the following cognitive abilities:
    1. Coherent speech, understand spoken or written language
    2. Recognize or identify objects, assuming intact sensory function
    3. Execute motor activities, assuming intact motor abilities, sensory function, and comprehension of the required task
    4. Abstract thinking, make sound judgments, plan, and carry out complex tasks
  - ii. Decline in cognitive abilities must be severe enough to interfere with daily life.

### II. Classification

- a. Dementia of the Alzheimer's type (DAT) (Alzheimer's Association, 2017; Hausman, 2006; Nelson-Marsh, 2005; Trahan et al, 2011)
  - i. Accounts for 60% to 80% of dementia diagnoses
  - ii. The three stages of Alzheimer's disease identified in the 2011 criteria and guidelines are (1) preclinical Alzheimer's disease, (2) mild cognitive impairment (MCI) due to Alzheimer's disease, and (3) dementia due to Alzheimer's disease.
    1. Characterized by structural and chemical changes in the brain, causing a steady and global decline in function
    2. Degenerative process occurring primarily in the cells located at the base of the forebrain that sends information to the cerebral cortex and hippocampus
    3. Decrease in acetylcholine production reduces the amount of neurotransmitter released to cells in the cortex, hippocampus, and nucleus basalis, resulting in a disruption of memory processes.

(continues on page 852)

4. Enzyme required to produce acetylcholine is dramatically reduced, especially in the area of the brain where neuritic plaques and neurofibrillary tangles occur in the greatest numbers.
  5. Formation of plaques composed of beta-amyloid and tangles appears to be related to the cholesterol transporting protein apolipoprotein-E (ApoE).
- b. Vascular dementia**
- i. Vascular dementia accounts for 17% of cases.
  - ii. Referred to as multi-infarct, poststroke dementia, or vascular cognitive impairment, resulting in decreased blood flow to parts of the brain
  - iii. Multiple infarcts to various areas of the brain result in a pattern of intermittent deterioration determined by the area of the brain that is affected.
- c. Lewy body disease (Lewy Body Dementia Association [LBDA], 2012; Mayo Clinic Staff, 2017; National Institute of Neurological Disorders and Stroke [NINDS], 2018)**
- i. Umbrella term for two related diagnoses, Parkinson's disease dementia (PDD) and dementia with Lewy bodies (DLB)
  - ii. Lewy body diseases (LBDs) are the second most common type of progressive dementia after Alzheimer's.
  - iii. Protein bodies (alpha synuclein) develop in nerve cells in the areas of the brain involved with thinking, memory, and movement.
  - iv. Differentiated from Alzheimer's disease or other nonsynucleinopathies by the diagnosis of REM sleep behavior disorder (RBD)
  - v. The central feature of DLB is progressive cognitive decline, combined with three additional defining features: (1) pronounced fluctuations in alertness and attention, (2) recurrent visual hallucinations, and (3) parkinsonian-type motor symptoms, such as rigidity and the loss of spontaneous movement.
- d. Frontotemporal dementia (Alzheimer's Association, 2017)**
- i. A group of disorders that cause progressive nerve cell loss in the frontal and temporal lobes of the brain
  - ii. Behavior variant frontotemporal dementia (FTD) is characterized by prominent changes in personality, interpersonal relationships, and conduct with nerve cell loss prominent in areas controlling conduct, judgment, foresight, and empathy for others. Often occurs in people in their 50s and 60s but can develop as early as their 20s or as late as their 80s.
  - iii. Primary progressive aphasia (PPA) is the other major form of frontotemporal degeneration more limited to the left hemisphere of the brain affecting speaking, writing, or comprehension.
  - iv. Prevalence of both FTD and PPA in the 45- to 65-year age range is nearly as common as younger-onset Alzheimer's disease
- III. Etiology**
- a. DAT: Exact cause unknown; most likely due to multiple factors rather than a single cause (Alzheimer's Association, 2017)
- i. Lifelong process—Incidence increases with longevity, and changes in the brain may develop decades before the onset of dementia.
  - ii. Genetics—familial pattern four times greater than general population (Nelson-Marsh, 2005)
1. Familial or early-onset Alzheimer's is linked to defects on genes on chromosome 1, 14, or 21, with some families exhibiting a pattern of inheritance suggesting possible autosomal dominant gene transmission (Lakhan, 2018).
2. Down syndrome: presents with an extra chromosome 21; may have a relationship to Alzheimer's disease
- A. At autopsy, both disorders have many of the same pathophysiological changes.
  - B. High percentage of individuals with Down syndrome who survive to adulthood develop Alzheimer's lesions by late 40s or early 50s (Alvarez, 2016).
3. Studies suggest that autoantibodies are produced in the brain, reflecting a possible alteration in the body's immune system.
- iii. Known risk factors: age and genetics. Familial Alzheimer's is a rare form of early onset disease and is known to be caused by mutations on one of three chromosomes: 1, 14, and 21 (Benetti, 2012).
- iv. Proposed risk factors: Studies to date have not confirmed causal relationship; however, various factors that have been suggested include cardiovascular disease, type 2 diabetes, and oxidative damage. Inflammation occurs as protein plaques appear, but it is not known whether inflammation is a cause or result. Other factors that may contribute are prior severe head trauma, low educational level, and female gender. Aluminum has been disproven as a cause.
- b. Vascular dementia**
- i. Predisposing factors: Various diseases and conditions that interfere with blood circulation, including cerebral and systemic vascular disease, hypertension, cerebral hypoxia, hypoglycemia, cerebral embolism, and severe head injury. Sometimes called "mixed dementia" (Mayo Clinic Staff, 2018).
- c. Frontotemporal dementia**
- i. Only known risk factor is family history, accounting for approximately 33% of cases, autosomal dominant linked to chromosome 17 (tau gene) and chromosome 3.
- IV. Statistics (Alzheimer's Association, 2017; Centers for Disease Control and Prevention [CDC], 2017)**
- a. Morbidity: In 2013, an estimated 5.2 million people in the United States were living with Alzheimer's disease. Current statistics suggest one in nine adults aged 65 and older are affected, with one in three age 85 or older affected (Atkinson, 2016). By 2025, the number of people age 65 and older with Alzheimer's disease is estimated to reach 7.1 million.
- b. Mortality: DAT is the sixth-leading cause of death and the fifth leading cause of death for people age 65 and older. In 2015, 110,561 Americans died, the most recent year for which final data are available (CDC, 2017).
- c. Cost: In 2017, the estimated cost of caring for Americans with Alzheimer's and other dementias was \$277 billion—and that doesn't include unpaid caregiving. Also, in 2017, more than 16 million Americans provided about 18.4 billion hours of unpaid care to Alzheimer's patients, worth \$232 billion. Total payments for healthcare, long-term care, and hospice for people with Alzheimer's and other dementias are projected to increase from \$277 billion in 2017 to \$1.1 trillion in 2050 (Alzheimer's Association, 2018).

## G L O S S A R Y

**Apolipoprotein-E (ApoE):** Lipoprotein with three isoforms with the ApoE<sub>4</sub> variant associated with an earlier-than-average age of onset for the common form of Alzheimer's disease.

**Amyloid plaque:** Buildup of amyloid protein and a primary hallmark of Alzheimer's disease.

**Atrophy:** Wasting or a decrease in the size of an organ or tissue.

**Beta-amyloid:** Insoluble protein that is an abnormal breakdown product of the cell membrane constituent amyloid precursor protein (APP) and is a component of the neurofibrillary tangles and plaques characteristic of Alzheimer's disease.

**Catastrophic reactions:** Extreme outbursts of emotion, most often anger or agitation. Also called "challenging behaviors," "disruptive behaviors," "behavioral symptoms related to dementia," "Alzheimer's behaviors," "behavioral issues," "behavioral and psychological symptoms of dementia" (BPSD).

**Emotional lability:** Excessive emotional reactivity associated with frequent changes or swings in emotions or mood.

**Hippocampus:** Part of the limbic system of the brain and one of several structures involved with emotion, memory, and learning.

**Hypermetamorphosis:** Compulsive exploration of environment, including touching.

**Hyperorality:** Consists of unexplained movements of the mouth and tongue and the act of placing nonfood items in the mouth.

**Lewy bodies:** Abnormal protein deposits that disrupt the brain's normal functioning, found in an area of the brain-stem where they deplete the neurotransmitter dopamine. In Lewy body disease, these abnormal proteins are diffuse throughout other areas of the brain, including the cerebral cortex. The brain chemical acetylcholine is depleted, causing disruption of perception, thinking, and behavior.

**Neuritic plaques:** Extracellular abnormalities composed of beta-amyloid in the gray matter of the brain.

**Neurofibrillary tangles:** Masses of fine fibrous elements found in cytoplasm signaling an abnormality of the hippocampus and neurons of the cerebral cortex that occurs especially in Alzheimer's disease. Classic finding at autopsy in the brain of client with DAT.

**Proprioception:** Awareness of posture, movement, changes in equilibrium, and the knowledge of position, weight, and resistance of objects in relation to the body.

**Sundowner's syndrome (also called sundowning syndrome):** Increased restlessness, wandering, aggression, or exacerbation of behavioral symptoms of Alzheimer's disease in the afternoon and evening.

**Synucleinopathies:** Alpha-synuclein is the primary structural component of Lewy body fibrils. It is an unstructured soluble protein that mutates in pathological conditions characterized by Lewy bodies, such as Parkinson's disease, dementia with Lewy bodies, and multiple system atrophy. These disorders are known as synucleinopathies (Arima et al, 1999).

**Tau:** Protein that channels chemical messages inside nerve cells.

## CARE SETTING

Client is cared for primarily in the home or assisted living/extended care; however, inpatient care may be required for treatment of other health problems.

## RELATED CONCERNS

Palliative/end-of-life care—hospice, page 970  
 Extended/long-term care, page 896

## CLIENT ASSESSMENT DATABASE

### DIAGNOSTIC DIVISION MAY REPORT

#### ACTIVITY/REST

- Feeling tired
- Decreased interest in usual activities, hobbies; inability to recall what is read or follow plot of television program
- Forced to retire from work

### MAY EXHIBIT

- Day-night reversal
- Wakefulness disturbance of sleep rhythms
- Lethargy
- Impaired motor skills
- Inability to carry out familiar, purposeful movements
- Content sitting and watching others

(continues on page 854)

**CLIENT ASSESSMENT DATABASE (contd.)****MAY REPORT (continued)****MAY EXHIBIT (continued)**

- Repetitive motions, such as folding, unfolding, refolding linen
- Wandering

**CIRCULATION**

- History of systemic vascular disease, cerebral vascular disease, hypertension, embolic episodes (may be predisposing factors)

**EGO INTEGRITY**

- Anxiety, depression—usually during early stages related to the knowledge that cognitive abilities are deteriorating
- Multiple losses, such as changes in body image and self-esteem
  - Inconsistent behavior
  - Verbal and nonverbal communication and behavior may be incongruent
  - Suspicious or fearful of imaginary people and situations
  - May cling to significant others SO(s)
  - Misperception of environment, misidentification of objects and people
  - Hoarding objects
  - Belief that misplaced objects are stolen
  - Emotional lability—may cry easily or laugh inappropriately
  - Variable mood changes, such as apathy, lethargy, restlessness, short attention span, or irritability
  - Catastrophic reactions
  - May deny significance of early changes and symptoms, especially cognitive changes
  - May conceal limitations, such as make excuses for not being able to perform tasks, redirect conversation, or avoid direct answers to questions
  - Feelings of helplessness; strong, depressive overlay; delusions; or paranoia

**ELIMINATION**

- Incontinence
- Diarrhea—related to impaction

**FOOD/FLUID**

- Changes in taste, appetite
- Denial of hunger, refusal to eat—may be trying to conceal lost skills

- Hypoglycemic episodes—predisposing factor
- Lack of interest in or forgetting mealtimes
- Dependence on others for food cooking and preparation at table, feeding, or using utensils
- Loss of ability to chew—silent aspiration concerns
- Weight loss
- Decreased muscle mass; emaciation in advanced stage

**HYGIENE**

- Dependence on others to meet basic hygiene needs

- Disheveled, unkempt appearance
- Body odor
- Poor personal habits
- Inappropriate clothing for situation or weather conditions
- Misinterpretation of, or ignoring, internal cues
- Forgetting steps involved in toileting self or inability to find the bathroom

**NEUROSENSORY**

- Family members may report a gradual decrease in cognitive abilities, impaired judgment, or inappropriate decisions; impaired recent memory but good remote memory; behavioral changes and altered or exaggerated individual personality traits

- Concealing abilities, may make excuses not to perform task or may thumb through a book without actually reading
- Loss of proprioception
- Primitive reflexes such as positive snout, suck, and palmar reflexes may be present

**MAY REPORT (continued)****SAFETY**

- Predisposing or factors that may accelerate the condition, such as a history of recent viral illness or serious head trauma, drug toxicity, stress, or nutritional deficits
- Incidental trauma such as falls or burns

**SOCIAL INTERACTIONS**

- Difficulty in relating to others
- Fragmented speech, aphasia, and dysphasia
- Demonstrates inappropriate behavior and ignores rules of social conduct
- Behavioral pattern alterations related to prior psychosocial factors and individuality and personality
- Family roles possibly altered/reversed as individual becomes more dependent

**TEACHING/LEARNING**

- Family history of DAT
- May present a total healthy picture, with exception of memory or behavioral changes
- Use or misuse of medications, over-the-counter (OTC) drugs, including alcohol
- Difficulty managing medications

**DISCHARGE PLAN CONSIDERATIONS**

- May require support and legal services, financial assistance, caregiver support groups, respite and home health care
- ◆ Following inpatient acute care, refer to underlying condition requiring admission for postdischarge considerations.

**MAY EXHIBIT (continued)**

- Facial signs or symptoms dependent on degree of vascular insults
- Seizure activity secondary to associated brain damage
- Disorientation to time initially then place; usually oriented to person until late in disease process
- Impaired recent memory, progressive loss of remote memory
- May change answers during the interview
- Difficulty in comprehension, abstract thinking
- Unable to do simple calculations or repeat the names of three objects; short attention span
- Hallucinations, delusions, severe depression, or mania may occur in advanced stage
- May have impaired communication—difficulty finding correct words, especially nouns; conversation repetitive or scattered with substituted meaningless words; speech may become inaudible; gradually loses ability to write or read

## DIAGNOSTIC STUDIES

Although no diagnostic studies are specific for Alzheimer's disease, these studies are used to rule out reversible problems that may be confused with these types of dementia.

TEST WHY IT IS DONE	WHAT IT TELLS ME
<b>DIAGNOSTIC STUDIES</b>	
• <b>Neurological mental status examination:</b> The client is asked to perform maneuvers or answer questions that are designed to elicit information about the condition of specific parts of the brain or peripheral nerves. Testing assesses mental status and alertness, muscle strength, reflexes, sensory perception, language skills, and coordination.	Many tests may be administered to evaluate client's brain functioning, each measuring a different aspect. One such test, the 7-minute screen (7MS), appears to be highly sensitive to Alzheimer's disease by differentiating between cognitive changes related to the normal aging process and those related to Alzheimer's disease (Solomon et al, 1998).
• <b>Electroencephalogram (EEG):</b> Measures electrical activity of the brain.	May reveal slow-wave delta activity indicative of later stages of Alzheimer's disease. May also reveal focal vascular lesions associated with vascular dementia.
• <b>Skull x-rays:</b> Determine presence of structural injury.	Usually normal but may reveal signs of head trauma.
• <b>Positron emission tomography (PET) scan:</b> Three-dimensional, computer-enhanced, full-color image of the brain.	Traces a positron-emitting chemical that binds effectively to abnormal protein plaques and tangles, thus detecting these Alzheimer markers.
• <b>Computed tomography (CT) or CAT scan:</b> X-ray procedure that uses a computer to produce a detailed picture of a cross section of the brain.	May show widening of ventricles or cerebral atrophy. These studies are also used to rule out other central nervous system (CNS) disease.
• <b>Single photon emission computed tomography (SPECT) scan:</b> Three-dimensional scan mapping blood flow in certain areas of the brain.	Can reveal abnormalities of oxygen uptake as well as levels of acetylcholine characteristic of Alzheimer's disease.
• <b>Cerebrospinal fluid (CSF):</b> Fluid produced within the brain, which surrounds the brain and spinal cord. Samples are obtained by means of lumbar puncture and evaluated for abnormal proteins.	Evidence supports that some cases of mild cognitive impairment may be an early form of Alzheimer's disease. Individuals likely to progress can be identified by measuring A $\beta$ 42, T-tau, and P-tau in the CSF (Kang et al, 2013).

## NURSING PRIORITIES

1. Provide safe environment and prevent injury.
2. Promote socially acceptable responses and limit inappropriate behavior.
3. Maintain reality orientation and prevent sensory deprivation or overload.
4. Encourage participation in self-care within individual abilities.
5. Promote coping mechanisms of client/SO(s).
6. Support client and family in grieving process.
7. Provide information about disease process, prognosis, and resources available for assistance.

## DISCHARGE GOALS

Not indicated in home or community setting. Following inpatient care, based on underlying condition requiring admission.

### NURSING DIAGNOSIS: risk for Injury

#### Possibly Evidenced by

Alteration in cognitive/psychomotor function

#### Desired Outcomes/Evaluation Criteria—Family/Caregiver(s) Will

#### Safe Home Environment NOC

Identify and correct environmental factors that increase risk of injury to client.

**NURSING DIAGNOSIS:** **risk for Injury** (continued)**Client Will****Physical Injury Severity NOC**

Be free of injury.

**Safe Wandering NOC**

Ambulate freely in environment without harm to self or others.

Accept redirection from unsafe activities.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Environmental Management: Safety NIC</b>	
<i>Independent</i>	
Assess degree of impairment in ability and competence and presence of impulsive behavior.	Identifies potential risks in the environment and heightens awareness of risks so caregivers are more alert to dangers. Clients demonstrating impulsive behavior are at increased risk of injury because they are less able to control their own behavior/actions.
Assist caregiver to identify any risks or potential hazards and visual-perceptual deficits that may be present.	Visual-perceptual deficits increase the risk of falls.
Eliminate or minimize identified hazards in the environment.	A person with cognitive impairment and perceptual disturbances is prone to accidental injury because of the inability to take responsibility for basic safety needs or to evaluate the unforeseen consequences, such as lighting a stove or cigarette and forgetting about it, mistaking plastic fruit for the real thing and eating it, or misjudging distance involving chairs and stairs. Preventive measures can contain client without constant supervision. Activities promote involvement and keep client occupied.
Lock outside doors as appropriate, especially in evening and night. Do not allow access to stairwell or exit. Provide supervision and activities for client who is regularly awake during the night. Recommend use of "childproof locks"; secure such items as medications, cleaning products, poisonous substances, tools, and sharp objects. Remove stove knobs and burners.	As the disease worsens, the client may compulsively handle or fidget with objects, including locks, or put small items in mouth, which potentiates possibility of accidental injury and death.
<b>Dementia Management NIC</b>	
Monitor behavior routinely; note timing of behavioral changes, increasing confusion, and hyperactivity. Initiate least restrictive interventions before behavior escalates.	Early identification of negative behaviors with appropriate action can prevent need for more stringent measures. Note: Sundowner's syndrome develops in late afternoon or early evening, requiring programmed interventions and closer monitoring at this time to redirect and protect client.
Distract or redirect client's attention when behavior is agitated or dangerous, for example, climbing out of bed. Place bed in low position and mattress on floor, as indicated.	Maintains safety while avoiding a confrontation that could escalate behavior or increase risk of injury.
Obtain and have client wear identification jewelry, such as bracelet or necklace showing name, phone number, and diagnosis.	Facilitates safe return of client if lost. Because of poor verbal ability and confusion, these persons may be unable to state name, address, and phone number. Client may wander, exhibit poor judgment, and be detained by police, appearing confused, irritable, or having violent outbursts.
Dress according to physical environment and individual need.	The general slowing of metabolic processes results in lowered body heat. The hypothalamic gland may be affected by the disease process or by aging, causing client to feel cold. Client may have seasonal disorientation and may wander out in the cold. Note: Leading causes of death in these clients include pneumonia and accidents (Neergard, 2013).

(continues on page 858)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Be attentive to nonverbal physiological symptoms.	Because of sensory loss and language dysfunction, client may express needs nonverbally such as thirst by panting and pain by sweating or doubling over. Note: Wandering may be a coping mechanism as client seeks a change in environment if too hot or cold, bored, or overstimulated, or searches for food or relief from discomfort.
Be alert to underlying meaning of verbal statements.	May direct a question to another, such as, "Are you cold or tired?" meaning client is cold or tired.
Monitor for medication side effects and signs of overmedication—extrapyramidal signs, orthostatic hypotension, visual disturbances, and gastrointestinal (GI) upsets.	Client may not be able to report signs or symptoms, and drugs can easily build up to toxic levels in the elderly. Dosages or drug choice may need to be altered.
Provide quiet room and reduced activity.	Overstimulation increases irritability and agitation, which can escalate to violent outbursts.
Avoid use of restraints. Have SO or others stay with client during periods of acute agitation.	Endangers the individual who succeeds in partial removal of restraints. May increase agitation and potentiate fall risk and fractures in the elderly.
<b>Collaborative</b>	
Administer medications as appropriate, such as:	
Risperidone (Risperdal), olanzapine (Zyprexa), quetiapine (Seroquel), or ziprasidone (Geodon), memantine (Namenda), galantamine (Razadyne), rivastigmine (Exelon), donepezil (Aricept)	Some antipsychotics are favored to control agitation, aggression, hallucinations, thought disturbances, and wandering because of their lower propensity to cause anticholinergic and extrapyramidal side effects. Note: May help moderate "sundowning," a condition related to deterioration of the hypothalamus, which controls the sleep-wake cycle. Other drugs, such as rivastigmine (Exelon) and donepezil (Aricept), prevent the breakdown of acetylcholine in the brain.

## NURSING DIAGNOSIS: chronic Confusion

### May Be Related To

Alzheimer's disease; multi-infarct dementia  
Head injury; cerebral vascular attack

### Possibly Evidenced By

Alteration in interpretation or response to stimuli  
Alteration in personality; impaired social functioning  
Progressive alteration in cognitive function  
Organic brain disorder

### Desired Outcomes/Evaluation Criteria—Client Will

#### Dementia Level NOC

Experience a decrease in level of frustration, especially when participating in daily activities.

#### Family/Caregiver Will

#### Caregiver Performance: Direct Care NOC

Verbalize understanding of disease process and client's needs.  
Identify and participate in interventions to deal effectively with situation.  
Provide for maximal independence while meeting safety needs of client.  
Initiate behaviors or lifestyle changes to maximize client's cognitive functioning.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Dementia Management NIC</b>	
<b>Independent</b>	
Assess degree of cognitive impairment, including changes in orientation to person, place, and time and attention span and thinking ability. Talk with SO and caregiver about changes from usual behavior and length of time problem has existed.	Provides baseline for future evaluation and comparison and influences choice of interventions. Note: Repeated evaluation of orientation may actually heighten negative responses and client's level of frustration.
Maintain a pleasant, quiet environment.	Reduces distorted input, whereas crowds, clutter, and noise generate sensory overload that stresses the impaired neurons.
Approach in a slow, calm manner.	This nonverbal gesture lessens the chance of misinterpretation and potential agitation. Hurried approaches can startle and threaten the confused client who misinterprets or feels threatened by imaginary people and/or situations.
Face the individual when conversing.	Maintains reality, expresses interest, and arouses attention, particularly in persons with perceptual disturbances.
Address client by name.	Names form our self-identity and establish reality and individual recognition. Client may respond to own name long after failing to recognize family or caregiver.
Use lower voice register and speak slowly to client.	Increases the chance for comprehension. High-pitched, loud tones convey stress and anger, which may trigger memory of previous confrontations and provoke an angry response.
Give simple directions, one at a time, or step-by-step instructions, using short words and simple sentences.	As the disease progresses, the communication centers in the brain become impaired, hindering the individual's ability to process and comprehend complex messages. Simplicity is the key to communicating, both verbally and nonverbally, with the cognitively impaired person.
Pause between phrases or questions.	Invites a verbal response and may increase comprehension.
Give hints and use open-ended phrases when possible.	Hints stimulate communication and give the person a chance for a positive experience.
Listen with regard despite content of client's speech.	Conveys interest and worth to the individual.
Interpret statements, meanings, and words. If possible, supply the correct word.	Assisting the client with word processing aids in decreasing frustration.
Reduce provocative stimuli, such as negative criticism, arguments, and confrontations.	Any provocation decreases self-esteem and may be interpreted as a threat, which may trigger agitation or increase inappropriate behavior.
Use distraction. Talk about real people and real events when client begins ruminating about false ideas, unless talking realistically increases anxiety or agitation.	Rumination promotes disorientation. Reality orientation increases client's sense of reality, self-worth, and personal dignity.
Change the subject if current topic increases anxiety or agitation.	Enables the client to focus on another topic and decreases anxiety.
Refrain from forcing activities and communications.	Force decreases cooperation and may increase suspiciousness and delusions.
Change activity if client loses interest in present activity.	Changing activity maintains interest and reduces restlessness and possibility of confrontation.
Use humor with interactions.	Laughter can assist in communication.
Focus on appropriate behavior. Give verbal feedback and positive reinforcement such as a pat on the back or applause. Use touch judiciously and respect individual's personal space and response.	Reinforces correctness and appropriate behavior. A focus on inappropriate behavior can encourage repetition. Although touch frequently transcends verbal interchange and conveys warmth and acceptance, the individual may misinterpret the meaning of touch. Intrusion into personal space may be interpreted as threatening because of the client's distorted perceptions.

(continues on page 860)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Respect individuality and evaluate individual needs.	Persons experiencing a cognitive decline deserve respect, dignity, and recognition of worth as an individual. Client's past and background are important in maintaining self-concept, planning activities, and communication.
Allow personal belongings.	Familiarity enhances security, sense of self, and decreases feelings of loss and deprivation.
Permit hoarding of safe objects.	This activity may preserve security and counterbalances irrevocable losses.
Create simple, noncompetitive activities paced to the individual's abilities. Provide entertaining, memory-stimulating music, videos, and TV programs. Engage in old hobbies and preferred activities, such as arts and crafts, music, supervised cooking, gardening, and spiritual programs.	Motivates client in ways that will reinforce usefulness and self-worth and stimulate reality.
Make useful activities or jobs out of hoarding and repetitive motions, such as collecting junk mail, creating scrapbook, folding and unfolding linen, bouncing balls, dusting, or sweeping floors.	May decrease restlessness and provide option for pleasurable activity. Having a "job" helps client feel useful.
Provide several drawers or baskets that are acceptable to rummage through. Fill with safe items that would be of interest to client, such as yarn balls, quilt blocks, fabrics with different textures and colors, baby clothes, pictures, costume jewelry (without pins), small tools, or sports magazines.	Availability of this kind of assortment provides stimulation that enhances the sense and promotes memories of past life experiences.
Help client find misplaced items; label drawers and belongings. Do not challenge client.	May decrease defensiveness when client believes he or she is being accused of stealing a misplaced, hoarded, or hidden item. To refute the accusation will not change the belief and may invite anger.
Monitor phone use closely. Post significant phone numbers in prominent place and secure long-distance numbers.	Can be used as reality orientation. However, client may forget time of day when making calls or may try to call dead relative. Impaired judgment does not allow for distinguishing long-distance numbers and makes client easy prey for phone sales pitches.
Evaluate sleep and rest pattern and adequacy. Note lethargy, increasing irritability or confusion, frequent yawning, and dark circles under eyes.	Lack of sleep can impair cognitive function and coping abilities. Fatigue may increase severity of symptoms, especially as evening approaches. (Refer to ND: disturbed Sleep Pattern.)
Monitor for medication side effects and signs of overmedication.	Drugs can easily build up to toxic levels in the elderly, aggravating confusion. Dosages or drug choice may need to be altered.
<b>Collaborative</b>	
Administer medications, as individually indicated, for example:	
Acetylcholinesterase (AChE) inhibitors, such as donepezil (Aricept), rivastigmine (Exelon), or galantamine (Razadyne)	Cholinesterase inhibitors prevent the breakdown of acetylcholine, a chemical messenger important for learning and memory. These Food and Drug Administration (FDA)-approved medications are being used for the treatment of mild to moderate cognitive impairment by delaying progression of symptoms in Alzheimer's disease (Atkinson, 2016).
N-methyl-D-aspartate (NMDA) inhibitors, such as memantine (Namenda, Axura)	This class of drugs works by regulating the activity of glutamate, a different messenger chemical involved in learning and memory. This medication is also FDA approved for treatment of moderate to severe Alzheimer's disease. It slows the progression of the disease and has been shown to improve cognitive and physical abilities in the later stages of the disease (Atkinson, 2016).

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Antipsychotic agents, such as aripiprazole (Abilify), clozapine (Clozari), haloperidol (Haldol), quetiapine (Seroquel), or ziprasidone (Geodon)	Psychotic symptoms, such as hallucinations, delusions, aggression, agitation, and hostility, may respond to neuroleptic management in most clients with dementia.
Anxiolytic agents, such as buspirone (BuSpar), lorazepam (Ativan), or oxazepam (Serax)	These drugs may be useful for management of anxiety, restlessness, verbally disruptive behavior, and resistance.
Investigational drugs approved for other uses, for example, nonsteroidal anti-inflammatory drugs (NSAIDs), such as ibuprofen (Motrin), estrogen, Ginkgo biloba, vitamin E, selegiline (Eldepryl), and prednisone	These drugs are being studied for possible benefit of treatment or for delaying the onset and progression of DAT (National Institute on Aging [NIA], 2018).
Refer to therapist for personal cognitive rehabilitation therapy.	Identifying individual's goals for improvement and developing specific strategies has been found to assist some clients with early stage dementia to maintain function (Kudlicka et al, 2017).

### NURSING DIAGNOSIS: [disturbed Sensory Perception (specify)]

#### May Be Related To

Altered sensory reception or integration  
Biochemical/electrolyte imbalance  
Excessive/insufficient environment stimuli

#### Possibly Evidenced By

Change in usual response to stimuli; change in behavior pattern  
Restlessness; irritability; disorientation  
Change in sensory acuity; hallucinations  
Impaired communication

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Sensory Function Status NOC

Demonstrate improved or appropriate response to stimuli.

#### Caregivers Will

##### Risk Control NOC

Identify and control external factors that contribute to alterations in sensory and/or perceptual abilities.  
Assist client to identify real items in their environment.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Reality Orientation NIC</b>	
<i>Independent</i>	
Assess degree of impairment and how it affects the individual, including hearing or visual deficits.	Although brain involvement is usually global, a small percentage of clients may exhibit asymmetrical involvement, which may cause unilateral neglect. Client may not be able to access internal cues, recognize hunger or thirst, perceive external pain, or locate body within the environment.
Encourage use of corrective lenses and hearing aids, as appropriate.	May enhance sensory input and limit or reduce misinterpretation of stimuli.
Maintain a reality-oriented relationship and environment.	Reduces confusion and promotes coping with the frustrating struggles of misperception and being disoriented or confused.
Provide clues for 24-hour reality orientation with calendars, clocks, notes, cards, signs, music, seasonal hues, and scenic pictures; color-code rooms.	Dysfunction in visual-spatial perception interferes with the ability to recognize directions and patterns, and the client may become lost even in familiar surroundings. Clues are tangible reminders that aid recognition and may permeate memory gaps, increasing independence.

(continues on page 862)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Provide quiet, nondistracting environment when indicated, including soft music or room with plain but colorful wallpaper or paint.	Helps to avoid visual or auditory overload by emphasizing qualities of calmness and consistency. Note: Patterned wallpaper may be disturbing to the client.
Provide touch in a caring way.	May enhance perception to self and body boundaries.
Engage client in individually meaningful activities, supporting remaining abilities and minimizing failures. Examples include meal preparation, setup and cleaning activities, making bed, and gardening or watering plants.	Supports client's dignity, familiarizes individual with home and community events, and enables him or her to experience satisfaction and pleasure (Casciani, 2008).
Use sensory games to stimulate reality, such as smelling mentholated ointment may prompt client to tell of the time mother used it on client; use of spring or fall nature boxes may stimulate reality.	Communicates reality through multiple channels (Casciani, 2008).
Indulge in periodic reminiscence, such as listening to old music, recalling historical events, and looking at photos, mementoes, or videos.	Stimulates recollections, awakens memories, aids in the preservation of self and individuality via past accomplishments, and increases feelings of security. Helpful in easing adaptation to a changed environment (Casciani, 2008).
Provide intellectual stimulation activities, such as word games, review of current events, story time, or travel discussions.	Stimulates remaining cognitive abilities and provides a sense of normalcy.
Include in Bible study group, church activities, and TV services for shut-ins, or arrange for visitation by clergy or spiritual advisor, as appropriate.	Provides opportunity to meet spiritual needs and to maintain connection with religious beliefs; may help reduce sense of isolation from humanity.
Encourage simple outings and short walks. Monitor activity.	Outings refresh reality and provide pleasurable sensory stimuli, which may reduce suspiciousness or hallucinations caused by feelings of imprisonment. Motor functioning may be decreased because nerve degeneration results in weakness, decreasing stamina.
Promote balanced physiological functions, such as tossing colorful foam or beach balls or beanbags, marching, dancing, or arm dancing with music.	Preserves mobility by reducing the potential for bone loss and muscle atrophy; provides diversional activity and opportunity for interaction with others.
Involve in activities with others as dictated by individual situation—one-to-one visitors, animal visitation, socialization groups at an Alzheimer center, or occupational therapy, including crafts, painting or finger paints, and modeling clay.	Provides opportunity for the stimulation of participation with others and may maintain some level of social interaction.

## NURSING DIAGNOSIS: Anxiety

### May Be Related To

Major change (e.g., health/economic/role status)  
Interpersonal transmission  
Unmet needs

### Possibly Evidenced By

Extraneous movement, restlessness, hypervigilance  
Apprehensive, irritability, increase in wariness  
Increase in tension; alteration in sleep pattern

### Desired Outcomes/Evaluation Criteria—Client Will

#### Anxiety Level NOC

Display decreased muscle tension and restlessness.  
Demonstrate more appropriate range of feelings and lessened anxiety.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Anxiety Reduction NIC</b>	
<i>Independent</i>	
Note change of behavior, suspiciousness, irritability, and defensiveness. Identify strengths the individual had previously.	Change in moods may be one of the first signs of cognitive decline, and the client, fearing helplessness, tries to hide the increasing inability to remember and engage in normal activities.
Identify the individual's previous strengths	Facilitates assistance with communication and management of current deficits.
Deal with aggressive behavior by imposing calm, firm limits.	Acceptance can reduce fear and lessen progression of aggressive behavior.
Provide safe containment when necessary.	Safety of client and staff is important for avoidance of injury.
Provide clear, honest information about actions and events.	Assists in maintaining trust and orientation as long as possible. When the client knows the truth about what is happening, coping is often enhanced, and guilt over what is imagined is decreased.
Discuss feelings of SO and caregivers. Acknowledge normalcy of feelings and concerns and provide information as needed.	Client senses but may not understand reaction of others. This may heighten client's sense of anxiety and fear.

**NURSING DIAGNOSIS: Grieving****May Be Related To**

Anticipatory loss (e.g., memory, job, status, and independence)  
Family perception of potential loss of loved one

**Possibly Evidenced By**

Psychological distress; anger  
Despair; suffering  
Alteration in activity level, sleep pattern

**Desired Outcomes/Evaluation Criteria—Client/Family Will****Grief Resolution NOC**

Express feelings, concerns openly, as able.  
Acknowledge difficulty of dealing with impaired cognition.  
Discuss sense of loss with significant others.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Grief Work Facilitation NIC</b>	
<i>Independent</i>	
Assess degree of deterioration or level of coping.	Information is helpful to understand how much the client is capable of doing to maintain highest level of independence and to provide encouragement to help individuals deal with losses.
Provide open environment for discussion. Use therapeutic communication skills of active-listening and acknowledgment.	Encourages client and caregivers to discuss feelings and concerns realistically.
Note statements of despair, hopelessness, "nothing to live for," and expressions of anger.	May be indicative of suicidal ideation. Angry behavior may be client's way of dealing with feelings of despair.
Respect desire not to talk.	May not be ready to deal with or share grief.
Be honest; refrain from false reassurances or dire predictions about the future.	Honesty promotes a trusting relationship. Expressions of gloom, such as "You'll spend the rest of your life in a nursing home," are not helpful because no one knows what the future holds.

(continues on page 864)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Discuss with client and SOs ways they can plan together for the future.	Having a part in problem-solving and planning can provide a sense of control over anticipated events.
Assist client and SO to identify positive aspects of the situation.	Ongoing research, possibility of slow progression may offer some hope for the future.
Identify strengths client and SO see in self and situation and support systems available.	Recognizing these resources provides opportunity to work through feelings of grief.
<b>Collaborative</b>	
Refer to other resources, such as support groups, counseling, and spiritual advisor.	May need additional support or assistance to resolve feelings.

## NURSING DIAGNOSIS: **Sleep Deprivation**

### May Be Related To

Dementia, sundowner's syndrome  
Aging-related sleep stage shifts  
Inadequate daytime activity  
Prolonged discomfort (e.g., physical, psychological)

### Possibly Evidenced By

Irritability; restlessness; agitation  
Fatigue; daytime drowsiness; lethargy  
Decrease in ability to function

### Desired Outcomes/Evaluation Criteria—Client Will

#### Sleep NOC

Establish adequate sleep pattern, with wandering reduced.  
Report or appear rested.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Sleep Enhancement NIC</b>	
<b>Independent</b>	
Provide for adequate rest. Restrict daytime sleep as appropriate; increase interaction time between client and family and staff during the day, then reduce mental activity late in the day.	Although prolonged physical and mental activity results in fatigue, which can increase confusion, programmed activity without overstimulation promotes sleep.
Avoid use of continuous restraints.	Restraints may potentiate sensory deprivation, agitation, and restrict rest. Note: The U.S. Department of Health and Human Services: Centers for Medicare & Medicaid Services (2006) finalizes the Patients' Rights guidelines of 1999 that require that clients be free from chemical or mechanical restraint unless warranted by a medical diagnosis; that, when used, restraints must be used for a specified period of time; and that the least restrictive means of control be used.
Evaluate level of stress and orientation as day progresses.	Increasing confusion, disorientation, and uncooperative behaviors may interfere with attaining restful sleep pattern.
Adhere to regular bedtime schedule and rituals. Tell client that it is time to sleep.	Reinforces that it is bedtime and maintains stability of environment. Note: Later-than-normal bedtime may be indicated to allow client to dissipate excess energy and facilitate falling asleep.
Provide evening snack, warm milk, bath, or back rub or general massage with lotion.	Promotes relaxation and drowsiness and helps to address skincare needs.
Reduce fluid intake in the evening. Toilet before retiring.	Decreases need to get up to go to the bathroom/incontinence during the night.
Provide soft music or "white noise."	Reduces sensory stimulation by blocking out other environmental sounds that could interfere with restful sleep.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Allow to sleep in shoes or clothing if client demands.	Provided no harm is done, altering the “normal” lessens the rebellion and allows rest.
<b>Collaborative</b>	
Administer medications, as indicated for sleep, for example:	
Antidepressants, such as trazadone (Desyrel) or quetiapine (Seroquel)	May be effective in treating pseudodementia or depression, thus improving ability to sleep.
Sedative-hypnotics, such as zolpidem (Ambien) or zaleplon (Sonata)	Used sparingly, low-dose, short-acting, rapid-onset hypnotics may be effective in treating insomnia or sundowner’s syndrome.
Avoid use of diphenhydramine (Benadryl).	Once used for sleep, this drug is now contraindicated because it interferes with the production of acetylcholine, which is already inhibited in the brains of clients with DAT.

### NURSING DIAGNOSIS: Self-Care deficit (specify type)

#### May Be Related To

Alteration in cognitive functioning  
Fatigue; decrease in motivation

#### Possibly Evidenced By

Impaired ability to: prepare food, bring food to mouth; wash body part(s), regulate water temperature; choose clothing, put on/take off clothing; complete toileting tasks

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Self-Care Status NOC

Perform self-care activities within level of own ability.

##### Caregiver Will

##### Caregiver Performance: Direct Care NIC

Identify and use personal and community resources to provide necessary assistance; support client’s independence.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Self-Care Assistance: [specify] NIC</b>	
<b>Independent</b>	
Identify reason for difficulty in self-care related to physical limitations in motion, depression, cognitive decline, or environment.	Underlying cause affects choice of interventions and strategies. Clients reported to be unable to perform specific ADLs are often able to do so given the right circumstances, such as adequate and knowledgeable caregiver support.
Determine hygienic needs and provide assistance as needed with activities, including care of hair, nails, and skin; brushing teeth; and cleaning glasses.	As the disease progresses, basic hygienic needs may be forgotten. Infection, gum disease, disheveled appearance, or harm may occur when client or caregivers become frustrated, irritated, or intimidated by degree of care required.
Inspect skin regularly.	Presence of such lesions as ecchymoses, lacerations, or rashes may require treatment as well as signal the need for closer monitoring and protective interventions.
Incorporate usual routine into activity schedule as possible. Wait or change the time to initiate dressing and hygiene if a problem arises.	Maintaining routine may prevent worsening of confusion and enhance cooperation. Because anger is quickly forgotten, another time or approach may be successful.
Be attentive to nonverbal physiological symptoms.	Sensory loss and language dysfunction may cause client to express self-care needs in nonverbal manner, such as thirst by panting, need to void by holding self or fidgeting, and pain by facial grimacing.
Be alert to underlying meaning of verbal statements.	May direct a question to another, such as “Are you cold?” meaning “I am cold and need additional clothing.”

(continues on page 866)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Supervise but allow as much autonomy as possible.	Eases the frustration over lost independence.
Allot plenty of time to perform tasks.	Tasks that were once easy, such as dressing or bathing, are now complicated by decreased motor skills or cognitive and physical changes. Time and patience can reduce chaos resulting from trying to hasten this process.
Assist with neat dressing and provide colorful clothes.	Enhances esteem; may diminish sense of sensory loss and convey aliveness.
Offer one item of clothing at a time in sequential order. Talk client through each step of the task. Allow the wearing of extra clothing if client demands.	Simplicity reduces frustration and the potential for rage and despair. Guidance reduces confusion and allows autonomy. Altering the “normal” may lessen rebellion.
Provide reminders for elimination needs. Involve in bowel and bladder program, as appropriate.	Loss of control and independence in this self-care activity can have a great impact on self-esteem and may limit socialization. (Refer to ND: Constipation.)
Assist with and provide reminders for pericare after toileting or incontinence.	Good hygiene promotes cleanliness and reduces risks of skin irritation and infection.

### NURSING DIAGNOSIS: risk for imbalanced Nutrition: less than body requirements/Overweight

#### Possibly Evidenced By

Inability to ingest food (e.g., regressed habits); insufficient dietary intake  
Disordered eating behaviors or perceptions; portion sizes larger than recommended  
Sedentary behavior occurring for >2 hours/d  
Psychological disorder

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Nutritional Status NOC

Ingest nutritionally balanced diet.  
Maintain or regain appropriate weight.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Nutrition Management NIC</b>	
<i>Independent</i>	
Assess caregiver’s and client’s knowledge of nutritional needs.	Identifies needs to assist in formulating individual teaching plan. Role reversals may occur: a child now cooks for a parent, or a husband taking over “duties” of his wife, increasing the need for information.
Perform Edinburgh Feeding Evaluation in Dementia (EdFED) scale, as appropriate, if client demonstrates weight loss or decline in mealtime function. Schedule regular repeat reviews at same time of day and in same environment, as needed.	Helps establish baseline and monitors behaviors in moderate to severe dementia and determines level of assistance required (Stockdell & Amella, 2008).
Determine amount of exercise or pacing client does.	Nutritional intake may need to be adjusted to meet needs related to individual energy expenditure.
Offer or provide assistance in menu selection.	Poor judgment may lead to poor choices; client may be indecisive or overwhelmed by choices and/or unaware of the need to maintain elemental nutrition. Note: In general, metabolic rate decreases with age, requiring caloric adjustment that must be balanced with activity.
Provide privacy when eating habits become an insoluble problem. Accept eating with hands, spills, and whimsical mixtures such as salad dressing in milk or salt and pepper on ice cream. Avoid solo dining or separating client from other people too early in the disease process.	Socially unacceptable and embarrassing eating habits develop as the disease progresses. Acceptance preserves esteem and decreases irritability or refusal to eat as a result of anger or frustration. Early separation can result in client feeling upset and rejected and can actually result in decreased food intake.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Offer small meals and/or snacks of one or two foods around the clock, as indicated.	Large feedings may overwhelm the client, resulting either in complete abstinence or gorging. Small feedings may enhance appropriate intake. Limiting number of foods offered at a single time reduces confusion regarding which food to choose.
Simplify steps of eating and serve food in courses.	Promotes autonomy and independence; decreases potential frustration or anger over lost abilities.
Anticipate needs, cut foods, and provide soft or finger foods.	Coordination decreases as the disease progresses, which impairs the client's ability to chew and handle utensils.
Provide ample time for eating.	A leisurely approach aids digestion and decreases the chance of anger precipitated by rushing.
Place food items in pita bread or paper sack for the client who paces.	Carrying food may encourage client to eat.
Avoid baby food and excessively hot foods.	Baby foods lack adequate nutritional content, fiber, and taste for adults and can add to client's humiliation. Hot foods may result in mouth burns and/or refusal to eat.
Observe swallowing ability; monitor oral cavity.	Diminished abilities may result in client or caregiver repeatedly placing food in client's mouth, which is not swallowed, increasing risk of aspiration.
Stimulate oral-suck reflex by gentle stroking of the cheeks or stimulating the mouth with a spoon.	As the disease progresses, the client may clench teeth and refuse to eat. Stimulating the reflex may increase cooperation and intake.
<b>Collaborative</b>	
Refer to dietitian or nutritionist, as indicated.	Assistance may be needed to develop nutritionally balanced diet individualized to meet client needs or food preferences..
Provide MIND diet as appropriate.	The MIND diet (a hybrid of the Mediterranean and Dietary Approaches to Stop Hypertension diets) has been reported to slow the progress of cognitive decline in some individuals (Morris et al, 2015). Note: This diet includes a glass of wine daily, which may not be appropriate for all clients

### NURSING DIAGNOSIS: bowel Incontinence/impaired urinary Elimination

#### May Be Related To

Multiple causality; alteration in cognitive functioning; deficient dietary habits; generalized decline in muscle tone  
Difficulty in toileting self-care; inability to locate bathroom  
Medications

#### Possibly Evidenced By

Inability to recognize or inattention to urge to defecate/void  
Urgency; incontinence

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Bowel [or] Urinary Elimination NOC

Establish adequate or appropriate pattern of elimination.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Urinary Elimination [or] Bowel Management NIC</b>	
<b>Independent</b>	
Assess prior pattern and compare with current situation.	Provides information about changes that may require further assessment and intervention.
Establish bowel and bladder training program. Promote client participation to level of ability.	Stimulates awareness, enhances regulation of body function, and helps to avoid accidents.

(continues on page 868)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Monitor appearance and color of urine. Note amount and consistency of stool.	Detection of changes provides opportunity to alter interventions to prevent complications or acquire treatment, as indicated. Note: Although it is difficult, the caregiver must try to monitor frequency of bowel movements during the stage of the illness when the client is still toileting self. It is not enough to ask client, "Did you have a bowel movement today?" Client cannot remember. Monitoring is essential to prevent constipation and potential for impaction.
Encourage adequate fluid intake during the day, with diet high in fiber and fruit juices. Limit intake during the late evening and at bedtime.	Essential for bodily functions and prevents potential dehydration and constipation. Restricting intake in evening may reduce frequency and incontinence during the night.
<b>Self-Care Assistance: Toileting NIC</b>	
Locate bed near a bathroom when possible; make signs or color code door. Place a picture of a commode on the door. Provide adequate lighting, particularly at night.	Promotes orientation and increases success in finding bathroom. Incontinence may be attributed to inability to find a toilet.
Take client to the toilet at regular intervals. Dictate each step one at a time and use positive reinforcement.	Adherence to a daily and regular schedule may prevent accidents. Frequently, the problem is forgetting how to toilet, such as pushing pants down or positioning.
Avoid a sense of hurrying or being rushed.	Hurrying may be perceived as intrusion, which leads to anger and lack of cooperation with activity.
Be alert to nonverbal cues, such as restlessness, holding self, or picking at clothes.	May signal urgency or inattention to cues and/or inability to locate bathroom.
Be discreet and respect client's privacy.	Although the client is confused, a sense of modesty is often retained.
Convey acceptance when incontinence occurs. Change promptly; provide good skin care.	Acceptance is important to decrease the embarrassment and feelings of helplessness that may occur during the changing process. Prompt changing reduces risk of skin irritation and breakdown.
<b>Collaborative</b>	
Administer stool softeners, bulk expanders (e.g., Metamucil), or glycerin suppository, as indicated.	May be necessary to facilitate or stimulate regular bowel movement.

## NURSING DIAGNOSIS: risk for Sexual Dysfunction

### Possibly Evidenced by

Alteration in body function (e.g., disease, medication)  
Absence of privacy, significant other (SO)

### Desired Outcomes/Evaluation Criteria—Client Will

#### Sexual Functioning NOC

Meet sexuality needs in an acceptable manner.  
Experience fewer or no episodes of inappropriate behavior.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Sexual Counseling NIC</b>	
<i>Independent</i>	
Assess individual needs, desires, and abilities of client and partner.	Alternative methods need to be designed for the individual situation to fulfill the need for intimacy and closeness.
Encourage partner to show affection and acceptance.	The cognitively impaired person retains the basic needs for affection, love, acceptance, and sexual expression.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Ensure privacy or encourage home visitation for residential client, as appropriate.	Sexual expression or behaviors may differ. The individual may masturbate or expose self. Privacy allows sexual expression without embarrassment and the objections of others.
Use distraction, as indicated. Remind client that, when in a public area, sexual behavior is unacceptable.	This tool is useful when there is inappropriate or objectionable behavior, such as self-exposure. Gently guide client toward room as you talk to them.
Provide time to listen to and discuss concerns of partner.	Partner may need information and/or counseling about alternatives for sexual activity and ways to deal with problems, such as impotence or sexual aggression.

### NURSING DIAGNOSIS: compromised family Coping

#### May Be Related To

Prolonged disease that exhausts the capacity of support person  
 Insufficient reciprocal support  
 Insufficient information available to support person  
 Insufficient understanding of information by support person  
 Coexisting situations affecting the significant person

#### Possibly Evidenced By

Assistive behaviors by support person produce unsatisfactory results  
 Limitation in communication between support person and client; support person withdraws from client  
 Protective behavior by support person incongruent with client's abilities  
 Client complaint about significant person's response to health problem  
 Support person reports inadequate knowledge/understanding that interferes with effective behaviors

#### Desired Outcomes/Evaluation Criteria—Family Will

##### Family Coping NOC

Identify strategies/resources within themselves to deal with the situation.  
 Demonstrate positive coping behaviors in dealing with problems.  
 Use outside support systems/resources effectively.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Family Support NIC</b>	
<i>Independent</i>	
Include family in teaching and planning for home care.	Can ease the burden of home management and increase adaptation. A comfortable and familiar lifestyle at home helps preserve the client's need for belonging.
Review past life experiences, role changes, and coping skills.	Identifies skills that may help individuals cope with grief of current situation more effectively.
Focus on specific problems as they occur, the "here and now."	Disease progression follows no set pattern. A premature focus on the possibility of long-term care or possible incontinence, for example, impairs the ability to cope with present issues.
Establish priorities.	Helps to create a sense of order and facilitates problem-solving.
Be realistic and honest in all matters.	Decreases stress that surrounds false hopes, such as that client may regain past level of functioning from advertised or unproven medication. Aids in preparing family for progression of condition and increasing care needs.
Reassess family's ability to care for client at home on an ongoing basis.	Behaviors like hoarding, clinging, unjust accusations, and angry outbursts can precipitate family burnout and interfere with ability to provide effective care.

(continues on page 870)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Provide time to listen with regard to concerns and anxieties.	SO and caregiver require constant support with the multifaceted problems that arise during the course of this illness to ease the process of adaptation and grieving.
Help caregiver/family understand the importance of maintaining psychosocial functioning.	Embarrassing behavior and the demands of care may cause withdrawal from social contact.
Discuss possibility of isolation. Reinforce need for support systems.	The belief that a single individual can meet all the needs of the client increases the potential for physical or mental illness due to caregiver role strain. Note: Mortality rate for primary caregivers is actually higher than for the client with DAT.
Provide positive feedback for efforts.	Reassures individuals that they are doing their best and provides reinforcement to continue efforts.
Acknowledge concerns generated by consideration or decision to place client in long-term care facility. Answer questions honestly and explore options, as appropriate.	Constant care requirements may be more than can be managed by the caregiver and support systems. Support is needed for this difficult, guilt-producing decision, which may create a financial burden as well as family disruption and dissension.
Encourage visitation by extended family and friends as tolerated by client.	Familiarity forms a base of reality and can provide a reassuring freedom from loneliness. Recurrent contact helps family members realize and accept situation. Note: Family members may require ongoing support in dealing with visitation and issues of client's deterioration and their own personal needs.
<b>Collaborative</b> Involve SO and family members in planning care and problem-solving. Verify presence of advance directives and durable medical power of attorney.	Consensus may be more readily achieved when family participates in decision making. It is important, however, to keep client's wishes in mind when making choices and to be aware of who actually has the power to make decisions for the cognitively impaired client. Note: Approximately 25% of individuals with Alzheimer's who died in 2014 died at home (Steenhysen, 2017).
Refer to local resources such as adult day program, respite care, homemaker services, or a local chapter of Alzheimer's Disease Education and Referral (ADEAR) and the National Family Caregivers Association (NFCA).	Coping with these clients is a full-time, frustrating task. Respite and day care may lighten the burden, reduce potential social isolation, and prevent family burnout and caregiver role strain. ADEAR provides group support and family teaching and promotes research. Local groups provide a social outlet for sharing grief and promote problem-solving with such matters as financial or legal advice and home care. NFCA also provides programs for educating caregivers and healthcare providers and a quarterly publication.
Refer for family counseling or to appropriate ethical committee, as indicated.	Differing opinions regarding client care and placement can result in conflict requiring professional mediation.

## NURSING DIAGNOSIS: **Ineffective Health Maintenance**

### May Be Related To

Alteration in cognitive functioning; impaired decision-making  
Decrease in gross and/or fine motor skills  
Ineffective coping strategies  
Insufficient resources

### Possibly Evidenced By

Pattern of lack of health-seeking behavior  
Insufficient social support

**NURSING DIAGNOSIS:** **ineffective Health Maintenance** (continued)**Desired Outcomes/Evaluation Criteria—Family/Caregiver(s) Will****Health-Promoting Behavior NOC**

Identify factors related to difficulty in maintaining a safe, healthy environment.

Assume responsibility for and initiate behaviors and screenings supporting client healthcare goals.

Demonstrate effective use of resources such as respite or home health care services, homemakers, and other resources.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Health System Guidance NIC</b>	
<i>Independent</i>	
Evaluate level of cognitive, emotional, and physical functioning, including level of independence.	Identifies strengths, areas of need, and how much responsibility the client may be expected to assume. (Refer to ND: Self-Care deficit.)
Assess environment, noting unhealthy factors and ability of client to care for self.	Determines what changes need to be made to accommodate disabilities/challenges. (Refer to ND: risk for Injury.)
Assist client to develop plan for keeping track of and dealing with health needs.	Schedule can be helpful to maintain system for managing routine healthcare services.
Identify support systems available to client and SO, including other family members and friends.	Planning and constant care is necessary to maintain this client at home. If family system is unavailable or unaware, client health needs, such as nutrition, dental care, or eye exams, can be neglected. Primary caregiver can benefit from sharing responsibilities and constant care with others. (Refer to ND: risk for caregiver Role Strain, following.)
Evaluate coping abilities, effectiveness, and commitment of caregiver(s) and support persons.	Progressive debilitation taxes caregiver(s) and may alter ability to meet client's and own needs. (Refer to ND: compromised family Coping.)
<i>Collaborative</i>	
Identify senior services such as Meals on Wheels and community resources for homemaking and cleaning or handyman tasks.	As client's condition worsens, caregiver will require additional support to maintain healthy environment for client and self, especially if family support is limited or not available.
Refer to supportive services, as needed.	Medical and social services consultant may be needed to develop ongoing plan or identify resources as needs change.
Identify in-home healthcare options, including medical, dental, and diagnostic services.	Delivery of healthcare needs "on site" may prevent exacerbation of confusion, increase cooperation, and provide more accurate picture of client's status.

**NURSING DIAGNOSIS:** **risk for caregiver Role Strain****Possibly Evidenced by**

Illness severity of the care receiver; extended duration of caregiving required; caregiving task complexity

Partner is caregiver, female

Care receiver exhibits deviant, bizarre behavior

Alteration in cognitive functioning in care receiver

Family/caregiver isolation; insufficient caregiver respite or recreation

**Desired Outcomes/Evaluation Criteria—Caregiver Will****Caregiver Role Endurance NOC**

Demonstrate effective use of family and community resources to assist in meeting client's needs.

Engage in behaviors or lifestyle changes to promote own well-being.

Take advantage of respite opportunities as available.

Demonstrate ability to manage difficult behaviors.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Caregiver Support NIC</b>	
<i>Independent</i>	
Determine family/caregiver's understanding of condition and expectations for the future.	Identifies teaching needs. Provides opportunity to update information and clarify misconceptions. During the prolonged caregiving experience, 7 of 10 clients with Alzheimer's continue to live at home, where family and friends provide almost 75% of their care (Alzheimer's Association, 2017). As the individual descends into the disease, he or she cannot translate a thought into a motor action, thus full-time supervision and care is required. For some family members and care partners, this supervision becomes overwhelming and exhausting (Rentz, 2008).
Provide bibliotherapy.	Materials that can be reviewed as time permits or questions arise can be very helpful in expanding knowledge and providing ongoing support.
Identify strengths of caregiver and care receiver.	Helps to use positive aspects of each individual to the best of abilities in daily activities.
Facilitate family conference to share responsibilities as indicated and to stress importance of self-nurturing for caregiver, including such factors as pursuing self-development interests, personal needs, hobbies, and social activities.	Helps family to focus on needs of caregiver as well as care receiver. When others are involved in care, the risk of one person becoming overwhelmed is lessened.
Determine available supports and resources currently used.	Organizations including Alzheimer's Foundation of America, Alzheimer's Association, NFCA, or local support groups can provide information regarding adequacy of supports, identify needs, and suggest possible options.
Identify alternate-care sources such as sitter or daycare facility, senior care services such as Meals on Wheels and respite care, and Alzheimer's programs or a home-care agency.	As client's condition worsens, caregiver may need additional help from several sources to maintain client at home, even on a part-time basis.

Refer to CP: Multiple Sclerosis, ND: risk for caregiver Role Strain for additional interventions.

### NURSING DIAGNOSIS: **risk for Relocation Stress Syndrome**

#### Possibly Evidenced by

Deficient mental capacity; compromised health status  
Insufficient support system  
Insufficient predeparture counseling  
Move from one environment to another

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Stress Level NOC

Experience minimal disruption of usual activities.  
Display limited increase in agitation or emotional lability.

#### Family/Caregiver Will

#### Family Participation in Professional Care NOC

Engage in proactive planning to match client care needs with available resources.  
Include client in prior planning and decision-making process to level of ability.  
Recognize need to provide stability for client during adaptation period.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Relocation Stress Reduction</b> <b>NIC</b> <i>Independent</i>	
Discuss ramifications of move to new surroundings.	Discussing pros and cons of this decision helps those involved to reach an informed decision and feel better about and plan for the future.
Encourage visitation to facility prior to planned move.	Familiarizes family and client with new options to enable them to make informed decision.
Provide clear, honest information about actions and events.	Decreases “surprises.” Assists in maintaining trust and orientation. When the client knows the truth about what is happening, coping may be enhanced.

Refer to CP: Extended/Long-Term Care; ND: risk for Relocation Stress Syndrome for additional interventions.

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on underlying cause for admission and comorbidities). Refer to appropriate care plan.

## SURGICAL INTERVENTIONS

- I. **Procedure**—therapeutic manipulation or use of instruments to diagnose or remedy physical disorders or defects
  - a. Indications
    - i. Diagnose or cure a specific disease process
    - ii. Correct a structural deformity
    - iii. Restore a functional process
    - iv. Reduce the level of dysfunction or pain
  - b. Classification
    - i. Generally elective or preplanned
      - 1. Inpatient procedure
      - 2. Ambulatory or outpatient
- ii. Potentially life-threatening conditions can arise requiring emergent intervention.
- III. **Pathophysiology**—dependent upon the type of injury or disease process that the client has experienced
- III. **Statistics** (Centers for Disease Control and Prevention [CDC], 2006)
  - a. Population—Approximately 80 million surgical procedures were performed in the United States at in-patient hospitals and affiliated ambulatory or freestanding facilities.

## G L O S S A R Y

- Ambulatory surgery:** Refers to surgical procedures performed on an outpatient basis in a hospital or free-standing ambulatory surgery center's general or main operating rooms, satellite operating rooms, cystoscopy rooms, endoscopy rooms, cardiac catheterization labs, or laser procedure rooms.
- Atelectasis:** Collapsed or airless condition of the lung or lung segment.
- Bronchospasm:** Abnormal narrowing with partial obstruction of the lumen of the bronchi due to spasm of the peribronchial smooth muscle.
- Cephalad diffusion:** Movement toward the head, in context of spinal anesthesia, indicates advancement of drug effect generally beyond desired level.
- Cubital:** Refers to the ulna or the forearm.
- Dehiscence:** Bursting open or separation of surgical incision or wound.
- Electrocautery:** Cauterization using a variety of electrical modalities to create thermal energy, including a directly heated metallic applicator or bipolar or monopolar electrodes.
- Fasciculation:** Involuntary contraction or twitching of muscle fibers, which are visible under the skin.
- Hemostasis:** Arrest or cessation of bleeding from an injured vessel.
- Hypercoagulation:** Increased ability of blood, for example, to coagulate.
- Hypoxia:** An oxygen deficiency in body tissues.
- Intraoperatively:** Occurring during surgery.
- Laryngospasm:** Spasm of the laryngeal muscles that may be life-threatening.
- Perioperative:** Period of time that constitutes the surgical experience; includes the preoperative, intraoperative, and postoperative phases of nursing care.
- Postoperative:** Period of time that begins with admission to the postanesthesia care unit (PACU) and ends after a follow-up evaluation in the clinical setting or home.

(continues on page 874)

## G L O S S A R Y (continued)

**Preoperative:** Period of time from when the decision for surgical intervention is made to when the individual is transferred to the operating room table.

**Prophylactically:** Any agent or regimen that contributes to the prevention of infection or disease.

**Surgical Care Improvement Project:** Multiyear, national quality partnership of organizations called the Surgical Care Improvement Project, or SCIP, with the goal of decreasing surgical complications. The focuses being reported for SCIP areas (as of 2011) are infection

prevention (administration of antibiotics, monitoring blood glucose levels, appropriate hair removal, removal of urinary catheters, and perioperative temperature management), cardiac care, and venous thromboembolism (VTE) prevention (QualityNet Specifications Manual, 2011).

**Time-out protocol:** Procedure for ensuring final verification of the correct client, procedure, site, and, if applicable, implants. Includes active communication among all members of the surgical team; procedure is not started until this has occurred.

## CARE SETTING

Client may be inpatient on a surgical unit or outpatient or have a short stay in an ambulatory surgical setting.

## RELATED CONCERNS

Alcohol: acute withdrawal, page 919  
Cancer, general considerations, page 945  
Diabetes mellitus and diabetic ketoacidosis, page 454

Respiratory acidosis (primary carbonic acid excess) (see *DavisPlus*)

Respiratory alkalosis (primary carbonic acid deficit) (see *DavisPlus*)

Sepsis/septic shock, page 772

Venous thromboembolism (VTE) disease including deep vein thrombosis (DVT) and pulmonary embolism (PE), page 120

Total nutritional support: parenteral/enteral feeding, page 525

Also refer to plan of care for specific surgical procedure performed.

## CLIENT ASSESSMENT DATABASE

Data depend on the duration and severity of underlying problem and involvement of other body systems. Refer to specific plans of care for data and diagnostic studies relevant to the procedure and additional nursing diagnoses.

### DIAGNOSTIC DIVISION MAY REPORT

#### CIRCULATION

- History of cardiac problems, heart failure (HF), pulmonary edema, peripheral vascular disease, or vascular stasis, which increases risk of thrombus formation

### MAY EXHIBIT

- Changes in heart rate due to sympathetic stimulation

#### EGO INTEGRITY

- Feelings of anxiety, fear, anger, apathy
- Multiple stress factors related to financial, relationship, lifestyle issues

- Restlessness, increased tension or irritability
- Sympathetic stimulation—changes in heart or respiratory rate

#### ELIMINATION

- History of kidney or bladder conditions
- Use of diuretics and/or laxatives
- Change in bowel habits

- Abdominal tenderness, distention
- Absence of bowel elimination
- Decreased or absent urinary elimination

**MAY REPORT (continued)****MAY EXHIBIT (continued)****FOOD/FLUID**

- History of pancreatic insufficiency or diabetes mellitus (DM), which may predispose client to hypoglycemia or ketoacidosis
- Use of diuretics

**PAIN/DISCOMFORT**

- History of painful body area—often the reason for surgical procedure—due to disease, inflammation, infection, or trauma

**RESPIRATION**

- History or presence of respiratory infections
- Chronic lung conditions
- Past and/or current smoking

**SAFETY**

- Differences in personal identifiers, procedure type, and/or site when compared to verification tools, such as the consent form, history and physical examination, surgery schedule
- Allergies or sensitivities to medications, iodine, food, tape, latex, and solution(s)
- Immune deficiencies—increased risk of systemic infections and delayed healing
- Presence of cancer or recent cancer therapy
- Family history of malignant hyperthermia or reaction to anesthesia, autoimmune diseases
- History of hepatic disease, which might affect drug detoxification and may alter coagulation
- History of blood transfusion(s) or transfusion reaction

**TEACHING/LEARNING**

- Use of medications, such as anticoagulants, steroids, NSAIDs, antibiotics, antihypertensives, cardiotonic glycosides, antidysrhythmics, bronchodilators, diuretics, decongestants, analgesics, anti-inflammatory drugs, anticonvulsants, or antipsychotics and antianxiety agents as well as over-the-counter (OTC) medications, herbal supplements (e.g., garlic, ginseng, Ginkgo biloba, ginger, and feverfew present risk of excessive postoperative bleeding), or alcohol or other drugs of abuse, with risk of liver damage affecting coagulation and choice of anesthesia as well as potential for postoperative withdrawal

**DISCHARGE PLAN CONSIDERATIONS**

- May require temporary assistance with transportation, dressing(s), supplies, self-care, and homemaker or maintenance tasks
- Possible placement in rehabilitation or extended-care facility
- ▶ Refer to section at end of plan for postdischarge considerations.

- Malnutrition, including obesity
- Dry mucous membranes due to limited intake or nothing-by-mouth (NPO) status preoperatively
- Guarding behavior, facial mask, sleep disturbance, restlessness, moaning

- Changes in respiratory rate (respiratory pathology, pain, or sympathetic stimulation)

- Presence of existing infectious process
- Fever
- Advanced age

## DIAGNOSTIC STUDIES

Studies depend on type of operative procedure, underlying medical conditions, current medications, age, and weight. Deviations from normal should be corrected, if possible, for safe administration of anaesthetic agents.

TEST WHY IT IS DONE	WHAT IT TELLS ME
<b>BLOOD TESTS</b> <ul style="list-style-type: none"><li>• <b>Complete blood count (CBC):</b> Battery of screening tests, which typically includes hemoglobin (Hgb); hematocrit (Hct); red blood cell (RBC) count, morphology, indices, and distribution width index; platelet count and size; and white blood cell (WBC) count and differential.</li><li>• <b>Electrolytes:</b> Substances that dissociate into ions in solution and acquire the capacity to conduct electricity. Common electrolytes include sodium, potassium, chloride, calcium, and phosphate.</li><li>• <b>Arterial blood gases (ABGs):</b> Measurement of the pH level and the oxygen and carbon dioxide concentrations in arterial blood.</li><li>• <b>Bleeding or coagulation studies—prothrombin time (PT) and activated partial thromboplastin time (aPTT):</b> Screening for coagulation problems indicated with history of abnormal bleeding, liver or kidney disease, use of anticoagulants, or when medical history is not available as well as for high-risk procedures, such as peripheral vascular surgery, cardiopulmonary bypass, or prostatectomy.</li></ul>	An elevated WBC count is indicative of inflammatory process. It may be diagnostic, as in appendicitis. A decreased WBC count suggests viral processes, requiring further evaluation because immune system may be dysfunctional. Low Hgb suggests anemia or blood loss, which impairs tissue oxygenation and decreases the amount of Hgb available to bind with inhalation anesthetics. It may suggest need for crossmatch for possible blood transfusion. An elevated Hct may indicate dehydration, whereas decreased Hct suggests fluid overload. Imbalances impair organ function; for example, decreased potassium affects cardiac muscle contractility, leading to decreased cardiac output.
	Evaluates current respiratory status, which may be especially important in smokers or clients with chronic lung diseases.
	May be prolonged, interfering with intraoperative and/or postoperative hemostasis. Hypercoagulation increases risk of thrombosis formation, especially in conjunction with dehydration and decreased mobility associated with surgery.
<b>OTHER DIAGNOSTIC STUDIES</b> <ul style="list-style-type: none"><li>• <b>Chest x-ray:</b> Procedure used to evaluate organs and structures within the chest for symptoms of disease.</li><li>• <b>Electrocardiogram (ECG):</b> Record of the electrical activity of the heart.</li><li>• <b>Urinalysis:</b> Examination of urine for various cells and chemicals such as RBCs, WBCs, infection, or excessive protein.</li><li>• <b>Pregnancy test:</b> Recommended in presence of recently absent or irregular menses, unreliable use of contraception, or for gynecological procedures to limit fetal exposure to teratogenic agents.</li></ul>	Should be free of infiltrates or pneumonia. Used for identification of masses and chronic obstructive pulmonary disease (COPD). Abnormal findings require attention before administering anesthetics. Presence of WBCs or bacteria indicates infection. Elevated specific gravity may reflect dehydration. Positive results affect timing of procedure and choice of pharmacological agents.

## NURSING PRIORITIES

1. Assure correct client, procedure, and site.
2. Reduce anxiety and emotional trauma.
3. Provide for physical safety.
4. Prevent complications.
5. Alleviate pain.
6. Facilitate recovery process.
7. Provide information about disease process, surgical procedure, prognosis, and treatment needs.

## DISCHARGE GOALS

1. Client dealing realistically with current situation.
2. Injury prevented.
3. Complications prevented or minimized.
4. Pain relieved or controlled.
5. Wound healing and organ function progressing toward normal.
6. Disease process, surgical procedure, prognosis, and therapeutic regimen understood.
7. Plan in place to meet needs after discharge.

## PREOPERATIVE

NURSING DIAGNOSIS:	readiness for enhanced Knowledge regarding condition, prognosis, treatment, self-care, and discharge needs
ACTIONS/INTERVENTIONS	RATIONALE
<b>Teaching: Preoperative NIC</b> <i>Independent</i>	
Assess client's level of understanding.	Facilitates planning of preoperative teaching program and identifies content needs.
Review specific pathology and anticipated surgical procedure. Verify correct client, procedure, and marked site and that appropriate consent has been signed.	Provides knowledge base from which client can make informed therapy choices and consent appropriate for correct procedure and site. Presents opportunity to clarify misconceptions.
Use institution's protocol for Preventing Wrong Site, Wrong Procedure, and Wrong Person Surgery and resource teaching materials and audiovisuals, as available.	Completion of specific checklists will minimize risk of error. Specifically designed materials can facilitate the client's learning.
Implement individualized preoperative teaching program:	Enhances client's understanding and control and can relieve stress related to the unknown or unexpected.
Preoperative and postoperative procedures and expectations, urinary and bowel changes, dietary considerations, activity levels, transfers, respiratory and cardiovascular exercises; anticipated intravenous (IV) lines and tubes such as nasogastric (NG) tubes, drains, and catheters	Absence or limitation of preoperative preparation and teaching increases the need for postoperative support in addition to managing underlying medical conditions.
Preoperative instructions, including bowel prep, NPO time, antibacterial soap shower and other skin preparation, which routine medications/OTC drugs and herbs to take or hold—prophylactic antibiotics or anticoagulants; anesthesia premedication	Helps reduce the possibility of postoperative complications and promotes a rapid return to normal body function. Depending on time and type of surgical procedure and anesthetic agent/route, medications may be held (e.g., warfarin may be held 4 to 5 days preoperatively and changed to low-molecular-weight heparin with last dose 12 hours prior to OR (Daley et al, 2018). Note: In some instances, liquids and medications are allowed up to 2 hours before scheduled procedure.
Intraoperative client safety—positional needs due to arthritis, previous injury, or current mobility; not crossing legs during procedures performed under local or light anesthesia	Reduced risk of complications or untoward outcomes, such as muscular, nerve (e.g., injury to the peroneal and tibial nerves with postoperative pain in the calves and feet), or joint soreness.
Expected or transient reactions such as low backache, localized numbness, and reddening or skin indentations	Minor effects of immobilization or positioning should resolve in 24 hours. If they persist, medical evaluation is required.
Inform client and SO about timely arrival on surgical day, itinerary, and physician-SO communications.	Logistical information about preoperative preparation time, operating room (OR) schedule and locations (e.g., recovery room, postoperative room assignment), as well as where and when the surgeon will communicate with SO relieves stress and miscommunications, preventing confusion and doubt over client's well-being.

(continues on page 878)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Discuss and develop individual postoperative pain management plan. Identify misconceptions client may have and provide appropriate information. Review use of 0 to 10 or similar pain assessment scale.	Increases likelihood of successful pain management. Some clients may expect to be pain-free or fear becoming addicted to opioid agents.
Provide opportunity to practice coughing, deep-breathing exercises, possible use of incentive spirometry, and muscular exercises.	Enhances learning and continuation of activity postoperatively.

## NURSING DIAGNOSIS: Anxiety [specify level]

### May Be Related To

Situational crisis (e.g., wrong client, procedure or site error; unfamiliarity with environment)  
Change in health status, threat of death  
Separation from usual support systems

### Possibly Evidenced By

Increase in tension, apprehensive, uncertain, fearful  
Worried about change in life events, being scared  
Facial tension, restlessness, self-focused  
Sympathetic stimulation (increased P/B, pulse, respirations)

### Desired Outcomes/Evaluation Criteria—Client Will

#### Anxiety Self-Control NOC

Acknowledge feelings and identify healthy ways to deal with them.  
Appear relaxed and be able to rest appropriately.  
Report anxiety reduced to a manageable level.  
Demonstrate ability to carry out procedure requirements.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Preoperative Coordination NIC</b> <i>Independent</i> Provide quiet environment and age-appropriate comfort measures.	Speaking in a calm, reassuring voice, allowing presence of family member or having parent hold child, etc., enhances level of comfort, helping to reduce anxiety.
Provide preoperative education, including intentional repetitive verification of client identifiers, procedure, marked site steps, and surgical “time-out” process. Arrange visit with OR personnel before surgery when possible. Discuss or demonstrate routine procedures and processes that may frighten or concern client, such as masks, lights, IVs, blood pressure (BP) cuff, electrodes, bovie pad, feel of oxygen cannula or mask on nose or face, autoclave and suction noises, or child crying.	Can provide reassurance (that client safety precautions are constantly ongoing), alleviate client’s anxiety, as well as provide information for formulating intraoperative care. Acknowledges that foreign environment may be frightening and alleviates associated fears. Decreased anxiety level reduces elevation of glucocorticosteroid levels, which can interfere with healing.
Inform client and SO of nurse’s intraoperative advocate role.	Develops trust and rapport, decreasing fear of loss of control in a foreign environment. Provides client and SO with contact person.
Assure client anticipating conscious sedation or spinal anesthesia that drowsiness or sleep occurs, that more sedation may be requested and will be given if needed, and that surgical drapes will block view of the operative field.	Reduces concerns that client may “see” the procedure.
<b>Surgical Preparation NIC</b> Identify anxiety levels that may necessitate postponement of surgical procedure.	Overwhelming or persistent fears result in excessive stress reaction and increasing glucocorticosteroid levels, potentiating risk of adverse reaction to procedure and anesthetic agents and impairing healing.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Validate source of concerns. Provide accurate factual information. Active-listen concerns.	Identification of specific fears helps client deal realistically with concerns, such as misidentification or wrong operation, dismemberment, disfigurement, loss of dignity and control, or being awake or aware with local anesthesia. Client may have misinterpreted preoperative information or have misinformation regarding surgery or disease process. Concerns regarding previous experiences of self, family, or acquaintances may be unresolved.
Note expressions of distress or feelings of helplessness, preoccupation with anticipated change or loss, and choked feelings.	Client may already be grieving for the loss represented by the anticipated surgical procedure, diagnosis, or prognosis of illness.
Introduce client to staff at time of transfer to operating suite.	Establishes rapport and psychological comfort with operative team.
Verbalize and document client identifiers to surgery schedule, client identification band, chart, marked site, and signed operative consent for surgical procedure according to facility's protocol and checklist.	Provides for positive identification, reducing fear that wrong procedure may be done as well as minimizing risk for wrong procedure and site.
Prevent unnecessary body exposure during transfer to and in OR suite.	Preserves client's modesty, reduces concern of loss of dignity and inability to exercise control, and reinforces nurse advocacy role.
Give simple, concise directions and explanations to sedated client. Review environmental concerns, as needed.	Impairment of thought processes makes it difficult for client to understand lengthy instructions.
Control external stimuli.	Extraneous noises and commotion may accelerate anxiety.
<b>Collaborative</b>	
Refer to surgeon, anesthesiologist, clinical manager, pastoral spiritual care, psychiatric clinical nurse specialist, or psychiatric counseling, if indicated.	Further evaluation, information, or counseling may be desired or required for client to deal with fear, especially concerning life-threatening conditions and serious and/or high-risk procedures.
Discuss postponement or cancellation of surgery with physician, anesthesiologist, client, and family, as appropriate.	May be necessary if overwhelming anxiety not reduced or resolved.
Refer wrong client, procedure, site, or implant discrepancies to surgeon, anesthesiologist, and appropriate persons.	Discrepancies must be corrected and verified by surgeon, client, and SO prior to OR entry. Note: Important to be aware of client's individual sensitivities that may affect drug dosage (e.g., clients with late effects of polio may have increased sensitivity to injection drugs, muscle relaxants, opioids) (Schwartz & Bosch, 2012).
Administer medications, as indicated, for example:	
Sedatives and hypnotics	Used to promote sleep the evening before surgery; may enhance coping abilities.
IV antianxiety agents	May be provided in the outpatient admitting or preoperative holding area to reduce nervousness and provide comfort. Note: Respiratory depression or bradycardia may occur, necessitating prompt intervention.
Antacids and H <sub>2</sub> blocker, preoperatively as indicated	Neutralizes gastric acidity and may reduce risk of aspiration or severity of pneumonia should aspiration occur, especially in obese or pregnant clients in whom there is an 85% risk of mortality with aspiration. Note: Ranitidine (Zantac) has been found to reduce postoperative infections in acute colorectal surgery.

## INTRAOPERATIVE

### NURSING DIAGNOSIS: risk for Perioperative Positioning Injury

#### Possibly Evidenced By

Disorientation, sensory/perceptual disturbances from anesthesia  
Immobilization, muscle weakness  
Obesity, emaciation, edema

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Physical Injury Severity NOC

Be free of injury related to perioperative disorientation.  
Be free of untoward skin or tissue injury or changes lasting beyond 24 to 48 hours following procedure.  
Report resolution of localized numbness, tingling, or changes in sensation related to positioning within 24 to 48 hours, as appropriate.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Positioning Intraoperative NIC</b> <i>Independent</i> Note anticipated length of procedure and customary position. Provide for potential complications.	Supine position may cause low back pain and skin pressure at heels, elbows, and sacrum; lateral chest position can cause shoulder and neck pain as well as eye and ear injury on the client's downside.
Review client's history, noting age, weight, height, nutritional status, and physical limitation or preexisting conditions that may affect choice of position and skin and tissue integrity during surgery.	Many conditions, such as lack of subcutaneous padding in elderly person, arthritis, thoracic outlet or cubital tunnel syndrome, diabetes, obesity, presence of abdominal stoma, peripheral vascular disease, level of hydration, and temperature of extremities, can make individual prone to injury.
Stabilize both client cart and OR table when transferring client to and from OR table, using an adequate number of personnel for transfer and support of extremities.	Unstabilized cart or table can separate, causing client to fall. Both side rails must be in the down position for caregiver(s) to assist client transfer and prevent loss of balance.
Anticipate movement of extraneous lines and tubes during the transfer and secure or guide them into position.	Prevents undue tension and dislocation of IV lines, NG tubes, catheters, and chest tubes; maintains gravity drainage when appropriate.
Secure client on OR table with safety belt and arm protection as appropriate, explaining necessity for safety precautions.	OR tables and arm boards are narrow, placing client at risk for injury, especially during fasciculation. Client may become resistive or combative when sedated or emerging from anesthesia, furthering potential for injury.
Protect body from contact with metal parts of the operating table.	Reduces risk of electrical injury.
Prepare equipment and padding for required position, according to operative procedure and client's specific needs. Pay special attention to pressure points of bony prominences on arms and ankles and neurovascular pressure points and soft tissues such as breasts and knees.	Depending on individual client's size, weight, and preexisting conditions, extra padding materials may be required to protect bony prominences, prevent circulatory compromise or nerve pressure, or to allow for optimal chest expansion for ventilation.
Position extremities so they may be periodically checked for safety, circulation, nerve pressure, and alignment. Monitor peripheral pulses and skin color and temperature.	Prevents accidental trauma to hands, fingers, and toes, which could inadvertently be scraped, pinched, or amputated by moving table attachments. Reduces risk of positional pressure on brachial plexus, peroneal, and ulnar nerves, which can cause serious neurovascular impairment in extremities, or prolonged plantar flexion, which may result in footdrop.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Place legs in stirrups simultaneously when lithotomy position used, adjusting stirrup height to client's legs, maintaining symmetrical position. Pad popliteal space and heels and feet, as indicated.	Prevents muscle strain and reduces risk of hip dislocation in elderly clients. Padding helps prevent peroneal and tibial nerve damage. Note: Prolonged positioning in stirrups may lead to compartment syndrome in calf muscles.
Provide foot board, elevate drapes off toes, and decrease blanket weight on extremities. Avoid or monitor equipment and instrumentation placement on trunk or extremities during procedure.	Pressure may cause neural, circulatory, and skin integrity disruption.
Reposition slowly at transfer from table and to bed.	Myocardial depressant effect of various agents increases risk of hypotension and/or bradycardia. Controlling movement enhances volume accommodation.
Determine specific postoperative positioning guidelines, such as elevation of head of bed following spinal anesthesia or nose and throat surgery, or turning to unoperated side following pneumonectomy.	Reduces risk of postoperative complications, such as headache associated with migration of spinal anesthesia or loss of maximal respiratory effort.
<b>Collaborative</b> Recommend position changes to anesthesiologist and/or surgeon, as appropriate.	Close attention to proper positioning can prevent muscle strain, nerve damage, circulatory compromise, and undue pressure on skin and bony prominences. Although the anesthesiologist is responsible for positioning, the nurse may be able to see or have more time to note client needs and provide assistance.

## NURSING DIAGNOSIS: risk for Injury

### Possibly Evidenced By

Wrong client, procedure, site, implants, equipment, or materials  
 External environment—physical design, structure of environment, exposure to equipment, instrumentation, positioning, use of pharmaceutical agents, alteration in cognitive function  
 Internal environment—tissue hypoxia, abnormal blood profile or altered clotting factors, broken skin

### Desired Outcomes/Evaluation Criteria—Care Provider Will

#### Safe Health Care Environment NOC

Implement surgical universal “time-out” protocol.  
 Identify individual risk factors.  
 Modify environment, as indicated, to enhance safety and use resources appropriately.

### Desired Outcomes/Evaluation Criteria—Client Will

#### Physical Injury Severity NOC

Be free of injury.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Surgical Precautions NIC</b> <b>Independent</b> Verify client identity and scheduled operative procedure by comparing client chart, arm band, and surgical schedule. Verbally ascertain correct name, procedure, operative site, and physician.	Ensures correct client, procedure, and appropriate extremity or side.
Remove dentures, partial plates, or bridges preoperatively per protocol. Inform anesthesiologist of problems with natural teeth such as loose teeth.	Foreign bodies may be aspirated during endotracheal intubation and extubation.

(continues on page 882)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Remove prosthetics or other devices preoperatively or after induction, depending on sensory or perceptual alterations and mobility impairment.	Contact lenses may cause corneal abrasions while under anesthesia; eyeglasses and hearing aids are obstructive and may break; however, clients may feel more in control of environment if hearing and visual aids are left on as long as possible. Artificial limbs may be damaged and skin integrity impaired if left on.
Remove jewelry preoperatively. Tape over, or isolate from skin, according to institution protocol. Remove piercing hardware.	Metals conduct electrical current and provide an electro-cautery hazard. Piercings may be “snagged,” resulting in soft tissue injury. In addition, loss or damage to client’s personal property can easily occur in the foreign environment. Note: In some cases (e.g., arthritic knuckles), it may not be possible to remove rings without cutting them off. In this situation, applying tape over the ring may prevent client from “catching” ring and prevent loss of stone or damage to finger and decrease psychological loss because of damage to personal property.
Document allergies, including risk for adverse reaction to latex, tape, and prep solutions.	Reduces risk for allergic responses that may impair skin integrity or lead to life-threatening systemic reactions.
Give simple and concise directions to the sedated client.	Impairment of thought process makes it difficult for client to understand lengthy directions.
Position client based on planned procedure and mindful of individual client needs.	Clients with arthritis, muscle contractures, etc. may require special padding/positioning to prevent injury.
Prevent pooling of skin prep solutions under and around client.	Antiseptic solutions may chemically burn skin as well as conduct electricity.
Assist with induction as needed, for example, standing by to apply cricoid pressure during intubation or stabilizing position during lumbar puncture for spinal block.	Facilitates safe administration of anesthesia.
Verify electrical safety of equipment used in surgical procedure, which includes intact cords, grounds, and medical engineering verification labels.	Malfunction of equipment can occur during the operative procedure, causing not only delays and unnecessary anesthesia but also injury or death. Short circuits, faulty grounds, laser malfunctions, or laser misalignment could occur. Periodic electrical safety checks are imperative for all OR equipment.
Place dispersive electrode or electrocautery pad over largest available muscle mass closest to surgical site, ensuring its contact.	Provides for shortest distance and maximum conductivity to ground to prevent electrical burns.
Confirm and document correct sponge, instrument, needle, and blade counts.	Foreign bodies remaining in body cavities at closure may result in inflammation, infection, perforation, abscess formation, and disastrous complications that can lead to death.
<b>Laser Precautions NIC</b>	
Verify credentials of laser operators for specific wavelength laser required for particular procedure.	Because of the potential hazards of lasers, physician and equipment operators must be certified in the use and safety requirements of specific wavelength laser and procedure, including open, endoscopic, abdominal, laryngeal, and intrauterine procedures.
Confirm presence of fire extinguishers and wet fire-smothering materials when lasers are used intraoperatively.	Laser beam may inadvertently contact and ignite combustibles outside of surgical site such as drapes and sponges.
Apply client and personnel eye protection before laser activation.	Eye protection for specific laser wavelength must be used to prevent injury.
Protect surrounding skin and anatomy appropriately utilizing wet towels, sponges, dams, and cottonoids.	Prevents inadvertent skin integrity disruption, hair ignition, and adjacent anatomy injury in area of laser beam use.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<b>Specimen Management NIC</b> Handle, label, and document specimens appropriately, ensuring proper medium and transport for tests required.	The OR nurse advocate must properly identify specimens to client, site, and test to ensure validity and maximum client outcome. Loss or mislabeling of specimens renders the surgical procedure fruitless and grossly compromises further treatment and client outcome. Frozen sections, preserved or fresh examination, and cultures all have different medium and transfer requirements.
<b>Fluid Management NIC</b> Observe intake and output (I&O) during procedure. Anticipate need for volume replacement or rapid infusion via infusion pumps and set up appropriately. Ascertain that pumps are functioning accurately.	Potential for fluid volume deficit or excess exists, affecting safety of anesthesia, tissue perfusion, organ function, and client well-being.
<b>Collaborative</b> Administer IV fluids, blood, or blood components, as indicated.  Collect autologous blood intraoperatively, as appropriate.	Maintains homeostasis and adequate level of sedation and muscle relaxation to produce optimal surgical outcome.  Blood lost intraoperatively may be collected, filtered, and reinfused either intraoperatively or postoperatively. A continuous, closed circuit must be maintained for the procedure to be acceptable for use by Jehovah's Witnesses. Note: Alternatively, red blood cell (RBC) production may be increased by the administration of epoetin (Epogen, Procrit) for up to 3 weeks preoperatively, reducing the need for blood transfusion whether autologous or donated.

<b>Surgical Precautions NIC</b> Validate surgical field medications and dosages with surgeon and anesthesiologist, including local anesthetics with or without epinephrine in regional blocks.	Prevents administration of contraindicated medications or inappropriate dosages. Note: Excessive doses of local anesthetic agents may potentiate cardiovascular compromise.
---	---

NURSING DIAGNOSIS: risk for Infection
<b>Possibly Evidenced By</b> Alteration in skin integrity, stasis of body fluids Environmental exposure, invasive procedures
<b>Desired Outcomes/Evaluation Criteria—Care Provider Will</b>
<b>Knowledge: Infection Management NOC</b> Identify individual risk factors and interventions to reduce potential for infection. Maintain safe aseptic environment.
<b>Desired Outcomes/Evaluation Criteria—Client Will</b>
<b>Infection Severity NOC</b> Be free of signs of healthcare-acquired infection.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Infection Control: Intraoperative NIC</b> <i>Independent</i> Adhere to surgical care policies and procedures.	These policies have been established nationwide for inpatient and outpatient surgeries to prevent or reduce infections. Note: The Surgical Care Improvement Project (SCIP) initiated measurement standards focused on reduction of surgically related infections through use and (continues on page 884)

**ACTIONS/INTERVENTIONS (continued)****RATIONALE (continued)**

Verify sterility of all items used in procedure.	timing of prophylactic antibiotics, appropriate hair removal, serum glucose management, perioperative temperature management, and timely removal of urinary catheters (QualityNet Specifications Manual, 2011).
Review laboratory studies for systemic infections and scrutinize operative area for possibility of localized infections.	Prepackaged items may appear to be sterile; however, each item must be scrutinized for manufacturer's sterility statement or central sterile processing indicators, package integrity, environmental effect on package, and delivery techniques. Note: Package sterilization and expiration dates and lot and serial numbers must be documented on implant items for further follow-up if necessary.
Verify that preoperative skin, vaginal, and bowel cleansing procedures have been done, as needed, depending on specific surgical procedure.	Increased WBC count may indicate ongoing infection, which the operative procedure will alleviate, such as appendicitis, abscess, and inflammation from trauma. Presence of local or systemic infection such as an upper respiratory infection (URI), urinary tract infection (UTI), skin lesions, or unknown infections may contraindicate or adversely affect the surgical procedure and/or anesthesia.
Prepare operative site according to specific procedure per agency protocol (e.g., scrubbing with liquid antibacterial soap, swabbing with betadine prep).	Cleansing reduces bacterial counts on the skin, vaginal mucosa, and alimentary tract.
Maintain normal client temperature range as much as possible.	Minimizes bacterial counts at operative site. Note: New CDC guidelines recommend skin prep in the OR should be performed using an alcohol-based agent unless contraindicated (CDC, 2017).
Examine skin for breaks or irritation and signs of infection.	CDC recommends maintaining normothermia in all clients (CDC, 2017). One study found that patients who experienced mild hypothermia during surgery were three times more likely to have positive cultures from the surgical site (Association of PeriOperative Registered Nurses [AORN], 2011).
Maintain dependent gravity drainage of indwelling catheters, tubes, and/or positive pressure of parenteral or irrigation lines.	Disruptions of skin integrity at or near the operative site are sources of contamination to the incision. Careful clipping of hair as close as possible to incision time will prevent skin cuts or abrasions, which provide potential entry for bacteria. Note: AORN recommendations state that hair at the surgical site should be left in place whenever possible. If hair must be removed, remove only the hair at the surgical site using clippers or depilatory (AORN, 2016).
Identify breaks in aseptic technique and resolve immediately upon occurrence.	Prevents stasis and reflux of body fluids.
Utilize universal precautions, contain contaminated fluids or materials to specific site in operating room suite, and dispose of them according to facility protocol.	Contamination by environmental or personnel contact renders the sterile field unsterile, thereby increasing the risk of infection.
Monitor blood glucose levels of diabetic clients, and maintain tight glycemic control, as indicated.	Containment of blood and body fluids, tissue, and materials in contact with an infected wound or client will prevent spread of infection to environment and other clients or personnel.
	Depending on length of procedure and type of IV fluids infused, intervention may be required to maintain preferred glucose levels. Note: Studies have supported that control of blood glucose contributes to better outcomes in critically ill and surgical patients (Frangou, 2008) with target levels less than 200 mg/dL (CDC, 2017).

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Apply sterile dressing.	Prevents environmental contamination of fresh wound. Note: The CDC recommends topical antimicrobial agents should not be applied to the surgical incision (CDC, 2017).
<b>Collaborative</b>	
Provide and document copious wound irrigation with saline, water, antibiotic, or antiseptic solution.	May be used intraoperatively to reduce bacterial counts at surgical site and cleanse the wound of bone, ischemic tissue, bowel contaminants, toxins, or other debris.
Obtain specimens for cultures and Gram stain.	Immediate identification of infective organism type by Gram stain allows prompt treatment, whereas more specific identification by cultures can be obtained in hours or days.
Administer appropriate antibiotics in timely manner, as indicated.	Antibiotics may be given prophylactically for selected elective surgical procedures or planned in clients at high risk for infection or when procedures need to be performed in the setting of known or suspected wound contamination. SCIP guidelines require the antibiotic to be administered within 1 hour of cut time (any time skin integrity is disrupted, such as in laparoscopic procedures) with the belief that it provides opportunity for the medication to travel through the body and be available at the surgical site at the time of incision (van Kasteren et al, 2007).

### NURSING DIAGNOSIS: risk for [perioperative] Hypothermia/Hyperthermia

#### Possibly Evidenced By

Low environmental temperature  
Pharmaceutical agent; sedation  
Extremes of age, weight; dehydration; [genetic trait]

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Thermoregulation NOC

Maintain body temperature within normal range.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Temperature Regulation: Perioperative NIC</b>	
<b>Independent</b>	
Note preoperative temperature related to age and disease process.	Used as baseline for monitoring intraoperative temperature. Preoperative temperature elevations may be indicative of disease process, such as appendicitis, abscess, or systemic disease requiring perioperative treatment. Note: Effects of aging on hypothalamus may decrease fever response to infection in the older adult client.
Assess environmental temperature and modify, as needed, by providing warming blankets or increasing room temperature.	Manipulating ambient air around client will prevent heat loss. Some clients may be cold intolerant such as elderly or very young, lack of subcutaneous tissue, and certain disease conditions (e.g., postpolio) (Schwartz & Bosch, 2012).
Cover exposed areas outside of operative field.	Heat losses will occur as skin on head, arms, and legs is exposed to cool environmental temperatures.
Provide cooling measures for client with preoperative or intraoperative temperature elevations.	Cool irrigations, exposure of skin surfaces to air, or cooling blanket may be required to decrease temperature.

(continues on page 886)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Increase ambient room temperature (e.g., to 78°F or 80°F [25.6°C to 26.7°C]) at conclusion of procedure.	Minimizes client heat loss when drapes are removed and client is prepared for transfer.
Apply warming blankets at emergence from anesthesia.	Inhalation anesthetics depress the hypothalamus, resulting in poor body temperature regulation.
<b>Collaborative</b> Monitor temperature throughout intraoperative phase.	Continuous warm or cool humidified inhalation anesthetics are used to maintain humidity and temperature balance within the tracheobronchial tree. Temperature fluctuations may indicate adverse response to anesthesia. Note: Use of atropine or scopolamine may further increase temperature.

#### Malignant Hyperthermia Precautions NIC

Respond promptly to symptoms of malignant hyperthermia (MH)—rapid temperature elevation and persistent high fever:	Prompt recognition and immediate action to control temperature is necessary to prevent serious complications or death.
Provide iced saline to all body surfaces and orifices.	Iced solution lavage of body surfaces and cavities will reduce body temperature.
Obtain dantrolene (Dantrium) for IV administration per protocol.	Immediate action to control temperature is necessary to prevent intense catabolic process associated with MH.

## POSTOPERATIVE

### NURSING DIAGNOSIS: **ineffective Breathing Pattern**

#### May Be Related To

Neuromuscular dysfunction (e.g., sedation); obesity  
Pain  
[Tracheobronchial obstruction]

#### Possibly Evidenced By

Abnormal breathing pattern (e.g., rate, depth); decrease in vital capacity  
Bradypnea; tachypnea

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Respiratory Status: Ventilation NOC

Establish an effective respiratory pattern free of cyanosis or other signs of hypoxia.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Postanesthesia Care NIC</b>	
<b>Independent</b>	
Maintain client airway by head tilt, jaw hyperextension, or oral pharyngeal airway.	Prevents airway obstruction.
Auscultate breath sounds. Listen for gurgling, wheezing, crowing, and/or silence after extubation.	Lack of breath sounds is indicative of obstruction by mucus or tongue and may be corrected by positioning and/or suctioning. Diminished breath sounds suggest atelectasis. Wheezing indicates bronchospasm, whereas crowing or silence reflects partial to total laryngospasm.
Observe respiratory rate and depth, chest expansion, use of accessory muscles, retraction or flaring of nostrils, and skin color; note airflow.	Ascertains effectiveness of respirations immediately so that corrective measures can be initiated.
Monitor vital signs continuously.	Increased respirations, tachycardia, and/or bradycardia suggest hypoxia.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Position client appropriately, depending on respiratory effort and type of surgery.	Head elevation and left lateral Sims' position prevents aspiration of secretions or vomitus, enhances ventilation to lower lobes, and relieves pressure on diaphragm.
Observe for return of muscle function, especially respiratory.	After administration of intraoperative muscle relaxants, return of muscle function occurs first to the diaphragm, intercostals, and larynx; followed by large muscle groups, neck, shoulders, and abdominal muscles; then by midsized muscles, tongue, pharynx, extensors, and flexors; and finally by eyes, mouth, face, and fingers.
Initiate “stir-up” regimen—turn, cough, deep breathe—as soon as client is reactive and continue in the postoperative period.	Hypoxia is common during the initial recovery period and respiratory control may be abnormal for weeks after surgery (e.g., reduced ventilation response to hypercapnia and hypoxia) (Miskovic & Lamb, 2017). Active deep ventilation inflates alveoli, breaks up secretions, increases O <sub>2</sub> transfer, and removes anesthetic gases; coughing enhances removal of secretions from the pulmonary system. Note: Respiratory muscles weaken and atrophy with age, possibly hampering elderly client's ability to cough or deep-breathe effectively.
Observe for excessive somnolence.	Opioid-induced respiratory depression or action of muscle relaxants in the body may be cyclical in recurrence, creating sine-wave pattern of depression and reemergence from anesthesia. In addition, thiopental sodium (Pentothal) is absorbed in the fatty tissues, and as circulation improves, it may be redistributed throughout the bloodstream.
Elevate head of bed as appropriate to surgical procedure. Get out of bed as soon as possible.	Promotes maximal expansion of lungs, decreasing risk of pulmonary complications.
Suction, as necessary.	Airway obstruction can occur as a result of blood or mucus in throat or trachea.
<b>Collaborative</b>	
Administer supplemental O <sub>2</sub> , as indicated.	Maximizes oxygen for uptake to bind with Hgb in place of anesthetic gases to enhance removal of inhalation agents.
Administer IV medications, such as naloxone (Narcan), doxapram (Dopram), or neostigmine (Prostigmin).	Narcan reverses opioid-induced central nervous system (CNS) depression; Dopram stimulates respiratory muscles. The effects of both drugs are cyclic in nature and respiratory depression may return. Prostigmin reverses nonpolarizing muscle blockers.
Provide and maintain ventilator assistance, as indicated.	Depending on cause of respiratory depression or type of surgery (e.g., pulmonary, extensive abdominal, cardiac), endotracheal tube (ET) may be left in place and mechanical ventilation continued for a time.
Assist with use of respiratory aids such as incentive spirometer.	Maximal respiratory efforts reduce potential for atelectasis and pulmonary infection. Client may need to be reminded and coached to reach specific goals.

### NURSING DIAGNOSIS: [disturbed Sensory Perception (specify)]

#### May Be Related To

Chemical alteration—use of pharmaceutical agents, hypoxia  
Therapeutically restricted environments; excessive sensory stimuli  
Physiological stress

(continues on page 888)

**NURSING DIAGNOSIS:** [disturbed Sensory Perception (specify)] (continued)**Possibly Evidenced By**

Disorientation (e.g., person, place, time); hallucinations  
Change in usual response to stimuli  
Change in problem-solving ability  
Motor incoordination

**Desired Outcomes/Evaluation Criteria—Client Will****Cognition NOC**

Regain usual level of consciousness and mentation.  
Recognize limitations and seek assistance as necessary.

**ACTIONS/INTERVENTIONS****RATIONALE****Postanesthesia Care NIC****Independent**

Reorient client continuously when emerging from anesthesia; confirm that surgery is completed.

As client regains consciousness, support and assurance of current physical status will help alleviate anxiety.

Speak in normal, clear voice without shouting, being aware of what you are saying. Minimize discussion of negatives about the client or personal or work-related problems within client's hearing. Explain procedures and environmental events even if client does not seem aware.

The nurse cannot tell when client is aware, but it is thought that the sense of hearing returns before client appears fully awake; so it is important not to say things that may be misinterpreted. Providing factual information helps client preserve dignity and prepare for next recuperative activity.

Evaluate sensation and movement of extremities and trunk, as appropriate.

Return of function following local or spinal nerve blocks depends on type and amount of agent used and duration of procedure.

Use bed rail padding, other medical protective devices as necessary.

Provides for client safety and protection from environment during emergence state. Prevents injury if client becomes combative while disoriented.

Secure parenteral lines, ET tube, and catheters, if present, and check for patency.

Disoriented client may pull on lines and drainage systems, disconnecting or kinking them.

Maintain quiet, calm environment.

External stimuli, such as noise, lights, and touch, may cause psychic aberrations when dissociative anesthetics (e.g., ketamine, tiletamine [Telazo]) have been administered.

Investigate changes in sensorium.

Continued confusion, specific to pediatric and geriatric age groups, may reflect drug interactions, hypoxia, anxiety, pain, electrolyte imbalances, or fear.

Observe for hallucinations, delusions, depression, or an excited state.

May develop following trauma/surgery and indicate delirium or may reflect sundowner's syndrome in elderly client. In client who has used alcohol or other drugs to excess, may suggest impending delirium tremens. Requiring further evaluation and intervention. Note: In one study, 24% of clients age 70+ years without history of dementia or delirium developed delirium postsurgery, prolonging length of stay and negatively impacting recovery (Gleason et al, 2015).

Reassess sensory, motor, and cognitive function thoroughly before discharge.

Phase II recovery or ambulatory surgical client must be able to care for self with the help of SO, if available, to prevent personal injury after discharge.

**Collaborative**

Evaluate need for extended stay in postoperative recovery area or need for additional nursing care before discharge, as appropriate.

Disorientation may persist, and SO may not be able to protect the client at home.

Contact or refer to case manager for alternate care options.

May not be ready or able to care for self, especially if no SO or family member is available to provide necessary assistance.

**NURSING DIAGNOSIS:** risk for deficient Fluid Volume**Possibly Evidenced By**

Deviations affecting intake of fluids (e.g., sedation, nausea)  
 Loss of fluid through abnormal routes—indwelling tubes, drains; through normal routes—vomiting  
 Active fluid loss (bleeding)  
 Extremes of age and weight

**Desired Outcomes/Evaluation Criteria—Client Will****Hydration NOC**

Demonstrate adequate fluid balance, as evidenced by stable vital signs, palpable pulses of good quality, normal skin turgor, moist mucous membranes, and individually appropriate urinary output.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Fluid Management NIC</b> <i>Independent</i>	
Measure and record I&O including tubes and drains. Calculate urine specific gravity, as appropriate. Review intraoperative record for potential causes of imbalance.	Accurate documentation helps identify fluid losses and replacement needs and influences choice of interventions. Note: Ability to concentrate urine declines with age, increasing renal losses despite general fluid deficit.
Assess urinary output specifically for type of operative procedure done.	May be decreased or absent after procedures on the genitourinary system and/or adjacent structures, such as ureteroplasty, ureterolithotomy, and abdominal or vaginal hysterectomy, indicating malfunction or obstruction of the urinary system.
Provide voiding assistance measures as needed such as privacy, sitting position, running water in sink, and pouring warm water over perineum, as needed.	Promotes relaxation of perineal muscles and may facilitate voiding efforts.
Monitor vital signs, noting changes in BP, heart rate and rhythm, and respirations. Calculate pulse pressure.	Hypotension, tachycardia, and increased respirations may indicate fluid deficit—dehydration or hypovolemia. Although a drop in BP is generally a late sign of fluid deficit or hemorrhagic loss, widening of the pulse pressure may occur early, followed by narrowing as bleeding continues and systolic BP begins to fall.
Note presence of nausea or vomiting.	Women, obese individuals, and those prone to motion sickness have a higher risk of postoperative nausea and vomiting. In addition, the longer the duration of anesthesia, the greater the risk for nausea. Note: Nausea occurring during first 12 to 24 hours postoperatively is frequently related to anesthesia (including regional anesthesia). Nausea persisting more than 3 days postoperatively may be related to the choice of opioid for pain control or other drug therapy.
Inspect dressings and drainage devices at regular intervals. Assess wound for swelling.	Excessive bleeding can lead to hypovolemia and circulatory collapse. Local swelling may indicate hematoma formation or hemorrhage. Note: Bleeding into a cavity (e.g., retroperitoneal) may be hidden and diagnosed only via vital sign depression or client reports of pressure sensation in affected area.
Monitor skin temperature; palpate peripheral pulses.	Cool or clammy skin and/or weak pulses indicate decreased peripheral circulation and need for additional fluid replacement.

(continues on page 890)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<b>Collaborative</b> Administer parenteral fluids, blood products including autologous collection, and/or plasma expanders, as indicated. Increase IV rate, if needed.	Replaces documented fluid loss. Timely replacement of circulating volume decreases potential for complications of deficit, including electrolyte imbalance, dehydration, and cardiovascular collapse. Note: Increased volume may be required initially to support circulating volume and prevent hypotension because of decreased vasomotor tone following halothane (Fluothane) administration.
Insert and maintain urinary catheter with or without urimeter, as necessary.	Provides mechanism for accurate monitoring of urinary output.
Resume oral intake gradually, or begin enteral feeding, as indicated.	Following surgical procedures not involving the gastrointestinal (GI) tract, the small bowel may be capable of absorbing nutrients regardless of absence of bowel sounds reflecting GI motility. If there is no evidence of abdominal distention, mechanical obstruction, or GI bleeding, early enteral feeding can hasten resolution of postoperative ileus and reduce risk of infection. As ileus resolves, oral fluids can be started.
Administer medications, as appropriate, for example:	
Antiemetics	Relieves nausea and vomiting, which may impair intake and add to fluid deficit. Note: Naloxone (Narcan) may relieve nausea related to use of anesthetic agents such as morphine (Duramorph) or fentanyl citrate (Sublimaze).
Epoetin alfa, vitamins B <sub>12</sub> and C, and folic acid	Medications used to stimulate production of RBCs are begun preoperatively, when needed, and may be administered postoperatively as well.
Monitor laboratory studies, such as Hgb and Hct or electrolytes. Compare preoperative and postoperative blood studies.	Indicators of hydration and circulating volume. Preoperative anemia and/or low Hct combined with unreplaced fluid losses intraoperatively will further potentiate deficit.

### NURSING DIAGNOSIS: acute Pain

#### May Be Related To

Physical agents (e.g., disruption of skin, tissue, and muscle integrity; musculoskeletal or bone trauma; presence of tubes and drains)

#### Possibly Evidenced By

- Self-report of pain intensity/characteristics
- Proxy report of pain behavior
- Expressive behavior (e.g., restlessness, crying)
- Guarding behavior; protective gestures
- Self-focus; narrowed focus
- Changes in vital signs

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Pain Level NOC

Report pain relieved or controlled.

Appear relaxed, able to rest or sleep and participate in activities appropriately.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Pain Management: Acute NIC</b> <i>Independent</i> Note client's age, weight, coexisting medical or psychological conditions, concomitant medications, idiosyncratic sensitivity to analgesics, and intraoperative course, including size and location of incision, drain placement, and anesthetic agents used.	Approach to postoperative pain management is based on multiple variable factors, especially medications used for chronic pain.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Review intraoperative and recovery room record for type of anesthesia and medications administered.	Presence of opioids and droperidol in system potentiates opioid analgesia, whereas inhalation anesthetics have no analgesic effects. In addition, intraoperative local and regional blocks have varying duration based on drug choice and dose. Note: Recovery time may be prolonged in clients with muscular diseases/conditions (e.g., postpolio) (Schwartz & Bosch, 2012).
Evaluate pain frequently in immediate postoperative phase and regularly (e.g., hourly per protocol) following transfer, noting characteristics, location, and intensity (0 to 10 [or similar] scale) using a validated pain assessment tool (Chou et al, 2016).	Provides information about need for, and effectiveness of, interventions. Note: It may not always be possible to eliminate pain; however, analgesics should reduce pain to a tolerable level. A frontal and/or occipital headache may develop 24 to 72 hours following spinal anesthesia, necessitating recumbent position, increased fluid intake, and notification of the anesthesiologist for alternative pain relief plan.
Note presence of anxiety, and relate with nature of and preparation for procedure.	Concern about the unknown, such as outcome of a biopsy and/or inadequate preparation due to emergent procedure, can heighten client's perception of pain.
Assess causes of possible discomfort other than operative procedure.	Discomfort can be caused or aggravated by other factors (e.g., presence of indwelling catheter causing bladder pain, NG tube resulting in gastric fluid and gas accumulation, or parenteral lines that have infiltrated IV fluids or medications).
Provide information about transitory nature of discomfort, as appropriate.	Understanding the cause of the transitory discomfort, such as sore muscles from administration of succinylcholine, which may persist up to 48 hours postoperatively; sinus headache, which may be associated with nitrous oxide; or sore throat, which may be due to intubation, provides emotional reassurance. Note: Paresthesia of body parts suggests nerve injury. Symptoms may last hours or months and require additional evaluation.
Reposition as indicated, such as semi-Fowler's or lateral Sims'.	May relieve pain and enhance circulation. Semi-Fowler's position relieves abdominal muscle tension and arthritic back muscle tension, whereas lateral Sims' will relieve dorsal pressures.
Provide additional comfort measures such as backrub and heat or cold applications.	Improves circulation, reduces muscle tension and anxiety associated with pain. Enhances sense of well-being.
Encourage use of relaxation techniques such as deep-breathing exercises, guided imagery, visualization, or music.	Relieves muscle and emotional tension; enhances sense of control and may improve coping abilities.
Provide regular oral care, occasional ice chips, or sips of fluids as tolerated.	Reduces discomfort associated with dry mucous membranes due to anesthetic agents and oral restrictions.
Monitor sedation, respiratory status. Note effectiveness and side or adverse effects of analgesia (Chou et al, 2016).	Respirations may decrease on administration of opioid, or synergistic effects with anesthetic agents may occur. Note: Migration of epidural analgesia toward head may cause respiratory depression or excessive sedation.
<b>Collaborative</b>	
Administer medications, as indicated, for example:	
IV analgesics after reviewing anesthesia record for contraindications and/or presence of agents that may potentiate analgesia	Analgesics given IV reach the pain centers immediately, providing more effective relief with smaller doses of medication. Note: Initial opioid dosage should be reduced by one-fourth to one-third after use of fentanyl (Innovar) or droperidol (Inapsine) to prevent respiratory depressant effects (Vallerand et al, 2017).
Avoid intramuscular route for analgesic medications.	Intramuscular (IM) administration is not recommended as it can cause significant pain and unreliable absorption (Chou et al, 2016).

(continues on page 892)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Around-the-clock analgesia via patient-controlled analgesia (PCA) or epidural analgesia (PCEA) with intermittent rescue doses, as needed	Research supports need to administer analgesics around the clock initially to prevent rather than merely treat pain. Use of PCA necessitates detailed client instruction. PCA is considered very effective in managing acute postoperative pain with smaller amounts of opioid and increased client satisfaction. However, new guidelines recommend avoiding the use of routine basal infusion of opioids with IV PCA in opioid-naïve adults (Chou et al, 2016). Note: Continuous epidural infusions may be used for 1 to 5 days following procedures that are known to cause severe pain such as certain types of thoracic or abdominal procedures.
Regional anesthetics, such as epidural block	Analgesics may be injected into the operative site, or nerves to the site may be kept blocked in the immediate postoperative phase to prevent severe pain.
NSAIDs, such as ketorolac (Toradol), diflunisal (Dolobid), or naproxen (Anaprox); acetaminophen (Tylenol)	Useful for mild to moderate pain in adults and children without contraindications (Chou et al, 2016) or as adjuncts to opioid therapy in moderate to severe pain. Allows for a lower dosage of opioids, reducing potential for side effects. Use alternating schedule with NSAIDs administered between opioid doses so peak effect occurs at a different time.
Monitor use and effectiveness of transcutaneous electrical nerve stimulation (TENS) unit when used.	TENS may be useful in reducing pain and amount of medication required postoperatively.

## NURSING DIAGNOSIS: impaired Tissue Integrity

### May Be Related To

Surgical procedure  
Mechanical factors (e.g., pressure, shear, friction)  
Impaired physical mobility  
Altered circulation

### Possibly Evidenced By

Damaged tissues (e.g., integumentary, subcutaneous, muscle)

### Desired Outcomes/Evaluation Criteria—Client Will

#### Wound Healing: Primary Intention NOC

Achieve timely wound healing.

#### Knowledge: Treatment Regimen NOC

Demonstrate behaviors or techniques to promote healing and prevent complications.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Incision Site Care NIC</b>	
<b>Independent</b>	
Identify client's individual risk factors for delayed healing.	Presence of comorbidities (e.g., diabetes, COPD, anemia, obesity, malnutrition, alcohol withdrawal, use of steroid therapy) and extremes of age can delay healing.
Inspect incision regularly, noting characteristics and integrity in relation to specific type of skin closure and postoperative stage.	Edges of incisions closed with tissue adhesives/glue may be joined within a week. Incisions closed with sutures or staples may require 10 days or longer. Early recognition of delayed healing or developing complications may prevent a more serious situation. Incisions may heal more slowly in clients with comorbidity or the elderly, in whom reduced cardiac output decreases capillary blood flow. Note: Inflammation

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Observe initial surgical dressings, noting accumulation of blood/other drainage. Reinforce initial dressing or change, as indicated, using clean or sterile technique per protocol or surgeon preference.	may be observed during first few days postoperatively, reflecting a normal phase of wound healing as long as client remains afebrile and pain level is not increasing (Delmore et al, 2017).
Gently remove tape in direction of hair growth and dressings when changing.	Close observation of surgical dressings promotes early identification of problems, such as hematoma formation, outright bleeding. Sterile surgical dressing should be left in place for first 24 to 48 hours and first dressing change may be reserved for surgeon.
Apply skin sealants or barriers before soft cloth tape, if needed. Use hypoallergenic tape, Montgomery straps, or elastic netting for dressings requiring frequent changing.	Reduces risk of skin trauma and disruption of wound.
Check tension of dressings. Apply tape parallel to incision beginning at center of incision to outer margin of dressing. Avoid wrapping tape around extremity.	Reduces potential for skin trauma or abrasions and provides additional protection for delicate skin and tissues.
Assess amounts and characteristics of drainage.	Prevents tape skin abrasions. Wrapping tape can impair or occlude circulation to wound and to distal portion of extremity.
Empty active low-pressure suction drains (e.g., Hemovac, Jackson-Pratt) when half full or more often per protocol.	Decreasing drainage suggests evolution of healing process, whereas continued drainage or presence of bloody or odoriferous exudate suggests complications, which may include hemorrhage, infection, and fistula formation.
Apply collection bag over passive drains or incisions in presence of copious or caustic drainage.	Suction action is diminished as device fills with drainage and pressure on the incision is increased.
Elevate extremities, as appropriate.	Facilitates approximation of wound edges; reduces risk of infection and chemical injury to skin and tissues.
Splint abdominal and chest incisions or area with pillow or pad during coughing and movement.	Promotes venous return and limits edema formation. Note: Elevation in presence of venous insufficiency may be detrimental.
Caution client not to touch incision.	Equalizes pressure on the wound, minimizing risk of dehiscence—especially important during stage I healing during the first 3 to 4 days—and for incisions closed with adhesives.
Cleanse skin surface, if needed, with running water and mild soap after incision is sealed.	Prevents contamination of area.
Monitor blood glucose levels of diabetic clients, as indicated.	Reduces skin contaminants; aids in removal of drainage or exudate.
These clients are at higher risk for healthcare-associated infections and delayed healing, and the risk increases if glucose level exceeds 220 mg/dL on the first postoperative day.	
<b>Collaborative</b>	
Apply ice, if appropriate.	Reduces edema formation that may cause undue pressure on incision during initial postoperative period.
Use abdominal binder, as indicated.	Provides additional support for high-risk incisions, especially in obese clients.
<b>Wound Care NIC</b>	
Irrigate open wounds; assist with debridement as needed.	Removes infectious exudate and necrotic tissue to promote healing.
Monitor and maintain dressings, whether hydrogel, vacuum dressing, or other types.	May be used to hasten healing in large, draining wound or fistula, to increase client comfort, and to reduce frequency of dressing changes. Also allows drainage to be measured more accurately and analyzed for pH and electrolyte content, as appropriate. (Refer to CP: Wound Care—Complicated or Chronic.)

**NURSING DIAGNOSIS:** risk for ineffective Tissue Perfusion (specify)**Possibly Evidenced By**

Hypovolemia  
Coagulopathy

**Desired Outcomes/Evaluation Criteria—Client Will****Circulation Status NOC**

Demonstrate adequate perfusion evidenced by stable vital signs; peripheral pulses present and strong, warm, and dry skin; usual mentation; and individually appropriate urinary output.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Hypovolemia Management NIC</b> <i>Independent</i> Change position slowly initially.	Vasoconstrictor mechanisms are depressed and quick movement may lead to orthostatic hypotension, especially in the early postoperative period.
Monitor vital signs, palpate peripheral pulses, and note skin temperature, color, and capillary refill. Evaluate urinary output and time of voiding. Document dysrhythmias.	Indicators of adequacy of circulating volume and tissue perfusion or organ function. Effects of medications and electrolyte imbalances may create dysrhythmias, impairing cardiac output and tissue perfusion.
Investigate changes in mentation or failure to achieve usual mental state.	May reflect a number of problems, such as inadequate clearance of anesthetic agent, oversedation with pain medication, hypoventilation, hypovolemia, or intraoperative complications such as emboli.
<b>Embolus Precautions NIC</b> Determine client's risk and assess for development of venous thromboembolism (VTE) symptoms (e.g., warm, red, painful lower leg; sudden-onset dyspnea with chest pain and cough).	Preventing complications of thromboembolic phenomena is part of improved surgical care according to the Surgical Care Improvement Project (Drake, 2011). Risk factors for VTE (which includes both deep vein thrombosis and pulmonary embolism) include the specific type of surgery (e.g., higher risk with hip or knee surgery), trauma to lower extremities, increasing age (older than age 40), hormonal therapy, chemotherapy, central line catheter placement, immobility, obesity, varicose veins, and pregnancy. (Refer to CP: Venous Thromboembolism [VTE] Disease including Deep Vein Thrombosis [DVT] and Pulmonary Embolism [PE].)
Assist with range-of-motion (ROM) exercises, including active ankle and leg exercises.	Stimulates peripheral circulation; aids in preventing venous stasis to reduce risk of thrombus formation.
Encourage and assist with early ambulation.	Enhances circulation and return of normal organ function.
Avoid use of knee gatch or pillow under knees. Caution client against crossing legs or sitting with legs dependent for prolonged period.	Prevents stasis of venous circulation and reduces risk of thrombophlebitis.
Assess lower extremities for erythema, edema, and calf tenderness.	Circulation may be restricted by some positions used during surgery, whereas anesthetics and decreased activity alter vasomotor tone, potentiating vascular pooling and increasing risks of thrombus formation.
<i>Collaborative</i> Apply antiembolic hose or sequential compression device (SCDs), as indicated.	Promotes venous return and prevents venous stasis of legs to reduce risk of thrombosis.
Administer low-dose unfractionated or low-molecular-weight heparin, as indicated.	Client identified as moderate or high risk will receive pharmacologic intervention to prevent or treat VTE (Drake, 2011).
<b>Hypovolemia Management NIC</b> Administer IV fluids and/or blood products, as needed.	Maintains circulating volume and supports perfusion.

**NURSING DIAGNOSIS:** **readiness for enhanced Health Management****Possibly Evidenced By**

Expresses desire to enhance management of prescribed regimens, risk factors

**Desired Outcomes/Evaluation Criteria—Client Will****Knowledge: Disease Process NOC**

Verbalize understanding of condition, effects of procedure, and potential complications.

**Knowledge: Treatment Regimen NOC**

Verbalize understanding of therapeutic needs.

Correctly perform necessary procedures and explain reasons for actions.

Initiate necessary lifestyle changes and participate in treatment regimen.

**ACTIONS/INTERVENTIONS****RATIONALE****Treatment: Disease Process NIC***Independent*

Ascertain client's readiness and ability to receive information about self-care management following surgery. Note barriers to learning, such as short hospitalization for surgical procedure, client's pain and fatigue, complexity and number of tasks client must perform at home (e.g., simple dressing change vs. open wound care), client's developmental and cognitive abilities and health literacy, and access and use of support and resources.

Throughout the postoperative recovery period, the nurse has a professional obligation to plan for discharge. This includes providing information to clients and their families to help them come to terms with their current condition and to prepare them for the future, in order to prevent complications. The length of the hospital stay is usually short; this impacts the time available for client/SO teaching and also means that much of the postoperative care and monitoring is done at home by clients and their families. Potential problems that may occur after discharge have little chance of getting addressed if not identified during the discharge planning process (Bowles et al, 2011).

Determine amount and type of information desired, and utilize desired teaching style, considering client's personal preferences and values, family situation and lifestyles, and cultural traditions.

These factors are involved in client-centered care. Studies have shown that certain aspects of postoperative care are important to clients (e.g., understanding their health progress [67%], appropriate activity level [66%], knowledge of insurance coverage [61%], information regarding medications and side effects [52%], understanding pain management [51%], and knowing when to consult the physician [49%]) (Boyle, 1992).

Review specific surgery or procedure performed and future expectations.

Provides knowledge base from which client can make informed choices.

Review and have client and SO demonstrate dressing change and incision and tube care, when indicated. Identify source for supplies.

Promotes competent self-care and enhances independence. Note: For incisions closed with a surgical zipper, client should be instructed as to when it is appropriate to peel off the device.

Emphasize avoidance of environmental risk factors, including exposure to crowds or persons with infections.

Reduces potential for acquired infections.

Discuss drug therapy, including use of prescribed and OTC analgesics and resumption of herbal supplements.

Enhances cooperation with regimen, reduces risk of adverse reactions or untoward effects. Note: Herbal preparations such as garlic, ginseng, Ginkgo biloba, ginger, and feverfew increase the risk of postoperative bleeding and are contraindicated for several days following surgery.

Identify specific activity limitations.

Prevents undue strain on operative site.

Recommend planned, progressive exercise program.

Promotes return of normal function and enhances feelings of general well-being.

Schedule adequate rest periods.

Prevents fatigue and conserves energy for healing.

Review importance of nutritious diet and adequate fluid intake.

Provides elements necessary for tissue regeneration and healing and support of tissue perfusion and organ function.

(continues on page 896)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Encourage cessation of smoking.	Smoking increases risk of pulmonary infections, causes vasoconstriction, and reduces oxygen-binding capacity of blood, affecting cellular perfusion and potentially impairing healing.
Identify signs and symptoms requiring medical evaluation, such as nausea or vomiting; difficulty voiding; fever; continued or odoriferous wound drainage; incisional swelling, erythema, or separation of edges; and unresolved pain or changes in characteristics of pain.	Early recognition and treatment of developing complications, which may include ileus, urinary retention, infection, and delayed healing, may prevent progression to more serious or life-threatening situation.
Emphasize necessity of follow-up visits with providers, including therapists and laboratory.	Monitors progress of healing and evaluates effectiveness of regimen.
Include SO in teaching program and discharge planning. Provide written instructions and teaching materials in client's dominant language. Instruct in use of and arrange for special equipment.	Provides additional resources for reference after discharge. Promotes effective self-care.
Identify available resources, including home-care services, visiting nurse, Meals on Wheels, outpatient therapy, and contact phone number for questions.	Enhances support for client during recovery period and provides additional evaluation of ongoing needs or new concerns.

**POTENTIAL CONSIDERATIONS** following surgical procedure (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

- **Fatigue**—disease states, anemia, stress
- **risk for Infection**—broken skin, traumatized tissues, stasis of body fluids, increased environmental exposure to pathogens, invasive procedures
- **Self-Care deficit**—pain or discomfort, weakness, decreased motivation
- **risk for delayed Surgical Recovery**—extremes of age, extensive surgical procedure, pain, diabetes mellitus, impaired mobility

Refer also to appropriate plans of care regarding underlying condition/specific surgical procedure for additional considerations.

## EXTENDED/LONG-TERM CARE

### I. Indications

- a. Level of care and needs of the client are frequently the deciding factors in the choice of placement.
- b. Short-term rehabilitation—individuals requiring services postdischarge from acute care setting
- c. Long-term nursing care—individuals requiring assistance with activities of daily living (ADLs)
  - i. Elderly individuals are the primary population requiring assistance with (on average) four to six ADLs.
  - ii. Increasing numbers of younger individuals are requiring care for debilitating conditions when they cannot be managed in the home setting (Family Caregiver Alliance, 2015).

### II. Statistics (Centers for Disease Control [CDC], 2006)

- a. Population: In 2004, 1.5 million people resided in nursing homes nationally, of which almost 75% were women. One recent study released by the National Center for Health Statistics' Long-Term Care Surveys states, "About 45% of nursing home residents in 2004 . . . were 85 years and older, white, and women. . . . More than two-thirds of the oldest nursing home residents, home health care patients, and discharged hospice care patients needed assistance in

performing three or more activities of daily living (ADLs) and were bladder incontinent" (Park-Lee et al, 2013). A 2013 report from the Centers for Disease Control and Prevention (updated in 2015), quoted by the Family Caregiver Alliance, states, "Annually 8,357,100 people receive support from the 5 main long-term care service; home health agencies (4,742,500), nursing homes (1,383,700), hospices (1,244,500), residential care communities (713,300) and adult day service centers (273,200)."

- b. Cost: In 2004, spending on long-term care services exceeded \$115.2 billion and accounted for 7.4% of national healthcare expenditures (Stewart, Grabowski, Lakdawalla, 2009). In 2016, the average daily rate for a private room in a skilled nursing facility was \$253, or \$92,350 annually; for a semiprivate room, \$225, or \$82,125 annually, according to data from the U.S. Department of Health and Human Services (DHHS, 2016). Studies published by insurance companies in 2017 showed that national median monthly rates for a private room were \$8121, or \$97,452 annually; rates for a semiprivate room rose to \$7150 monthly, or \$85,800 annually.

**G L O S S A R Y**

- Activities of daily living (ADLs):** Basic everyday self-care activities, including bathing, grooming, dressing, feeding, toileting, hygiene, and personal safety.
- Instrumental activities of daily living (IADLs):** Activities needed to function independently in the home or community, including shopping, meal preparation, housekeeping/home maintenance, laundry, managing medications and health maintenance, use of transportation, and money management.
- Long-term or extended care facility:** Provision of custodial or personal care services, with ongoing supervision and

coordination of care by licensed nurses (RN or LPN/LVN).

**Polypharmacy:** Use of multiple medications for one condition, or more medications than are medically necessary, a growing concern for older adults.

**Short-term rehabilitation or skilled nursing facility:**

Provision of registered nursing and rehabilitation services, such as physical, occupational, and/or speech therapies; intravenous (IV) antibiotics or chemotherapy; complicated wound care; and respiratory and nutritional support.

**CARE SETTING**

Primary focus of care is an extended or long-term care facility. However, many of the interventions are appropriate for assisted living or home-care situations.

MAY REPORT****MAY EXHIBIT****TEACHING/LEARNING**

- **Discharge plan considerations:** May require assistance with treatments, self-care activities, health maintenance, and nutritional support

► Refer to section at end of plan for postdischarge considerations.

## DIAGNOSTIC STUDIES

Dependent on age, general health, and medical condition. Individuals are often transferred to facility or admitted following an acute care episode where diagnostic studies were previously performed.

TEST WHY IT IS DONE	WHAT IT TELLS ME
<b>TESTS</b> <ul style="list-style-type: none"><li>• <b>Complete blood count (CBC):</b> Battery of screening tests, which typically includes hemoglobin (Hgb); hematocrit (Hct); red blood cell (RBC) count, morphology, indices, and distribution width index; platelet count and size; and white blood cell (WBC) count and differential.</li><li>• <b>Chemistry profile:</b> Evaluates general organ function and imbalances.</li></ul>	Hgb suggests anemia. Elevated Hct may indicate dehydration, whereas decreased Hct suggests fluid overload. An elevated WBC count is indicative of inflammatory process. Decreased WBC count suggests viral processes, requiring further evaluation because immune system may be dysfunctional. Age-related changes include decreased serum albumin, up to 20% increase in alkaline phosphatase, and decreased urine creatinine clearance.
<b>OTHER DIAGNOSTIC TESTS</b> <ul style="list-style-type: none"><li>• <b>Urinalysis:</b> Provides information about kidney function.</li><li>• <b>Pulse oximetry:</b> Determines oxygenation and respiratory function.</li><li>• <b>Communicable disease screens:</b> Rule out tuberculosis (TB), HIV, venereal disease, and hepatitis.</li><li>• <b>Drug screen:</b> As indicated by usage to identify therapeutic or toxic levels.</li><li>• <b>Visual acuity testing:</b> Assesses sight and health of the eyes.</li><li>• <b>Tonometer test:</b> Measures intraocular pressure.</li><li>• <b>Chest x-rays:</b> Procedure used to evaluate organs and structures within the chest for symptoms of disease.</li><li>• <b>Electrocardiogram (ECG):</b> Provides baseline data; detects abnormalities.</li></ul>	Determines presence of urinary tract infection (UTI) or diabetes mellitus (DM). <i>Note:</i> Bacteria are common in some populations, especially the elderly and bedridden, reflecting urinary stasis. Decreased levels indicate need for supplemental oxygen therapy. Testing identifies treatment needs and provides for safety of staff and other residents. Therapeutic drug monitoring aids in establishing individually appropriate drug dosage and frequency to maintain steady state for maximal drug effect and with minimal side effects. Identifies cataracts or other vision problems. Elevation indicates glaucoma. Reveals size of heart and lung abnormalities or disease conditions, or changes of the large blood vessels and bony structure of the chest. ST-segment and T-wave changes, atrial and ventricular dysrhythmias, and various heart blocks are common in the elderly population.

## NURSING PRIORITIES

1. Promote physiological and psychological well-being.
2. Provide for security and safety.
3. Prevent complications of disease and/or aging process.
4. Promote effective coping skills and independence.
5. Encourage continuation of healthy habits and participation in plan of care to meet individual needs and wishes.

## DISCHARGE GOALS

1. Client dealing realistically with current situation.
2. Homeostasis maintained.
3. Injury prevented.
4. Complications prevented or minimized.
5. Client performing ADLs by self or with assistance, as necessary.
6. Plan in place to meet needs after discharge, as appropriate.

## NURSING DIAGNOSIS: risk for Relocation Stress Syndrome

### Possibly Evidenced By

Decreased health status

Move from one environment to another; insufficient predeparture counseling; unpredictability of experience

Compromised health status

History of losses

Powerlessness

**NURSING DIAGNOSIS:** **risk for Relocation Stress Syndrome** (continued)**Desired Outcomes/Evaluation Criteria—Client Will****Anxiety Level NOC**

Demonstrate appropriate range of feelings and appear relaxed.

**Psychosocial Adjustment: Life Change NOC**

Verbalize understanding of reasons for change as able.

Participate in routine and special or social events as capable.

Verbalize acceptance of situation.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Relocation Stress Reduction NIC</b>	
<i>Independent</i>	
Ascertain if client has completed an advance directive. Provide information, as appropriate.	Assures client/family wishes will be known to provide direction to caregivers.
Determine client's and SO's attitude toward admission to facility and expectations for the future.	If this is expected to be a temporary placement, client's and SO's concerns will be different than if placement is permanent. When client is giving up own home and way of life, feelings of helplessness, loss, and grief are to be expected.
Help family and SO to be honest with client regarding admission. Be clear about actions and events.	Family may have difficulty dealing with decision and reality of permanent placement and may avoid discussing situation with client. Honesty decreases "surprises," assists in maintaining trust, and may enhance coping.
Identify support person(s) important to client and include in care activities, mealtime, and so on, as appropriate.	During adjustment period and times of stress, client may benefit from presence of trusted individual who can provide reassurance and reduce sense of isolation.
Assess level of anxiety and discuss reasons when possible.	Identifying specific problems enables individual to deal more realistically with them and care provider to intervene as necessary; for example, a client who is being neglected or abused or has unrelieved pain may be very anxious and afraid or unable to verbalize.
Develop nurse-client relationship.	Trusting relationships among client, SO, and staff promotes optimal care and support.
Make time to listen to client about concerns, and encourage free expression of feelings, including anger, hostility, fear, and loneliness.	Being available in this way allows client to feel accepted and begin to acknowledge and deal with feelings related to circumstances of admission.
Acknowledge reality of situation and feelings of client. Accept expressions of anger while limiting aggressive, acting-out behavior.	Permission to express feelings allows for beginning of resolution. Acceptance promotes sense of self-worth. Note: Psychosocial and/or physiological disturbances can occur as a result of transfer from one environment to another, especially if the move is unexpected or involuntary.
Assist client to identify strengths and successful coping behaviors and incorporate into problem-solving.	Building on past successes increases likelihood of positive outcome in present situation. Enhances sense of control and management of current deficits.
Orient to physical aspects of facility, schedules, and activities. Introduce to roommate(s) and staff. Give explanation of roles.	Getting acquainted is an important part of admission. Knowledge of where things are and from whom client can expect assistance can be helpful in reducing anxiety.
Provide above information in written or audiovisual form as well.	Overload of information is difficult to handle. Client can refer to written or audiovisual materials as needed to refresh memory or learn new information.

(continues on page 900)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Give careful thought to room placement. Provide help and encouragement in placing client's own belongings around room. Do not transfer from one room to another without client approval and documentable need.	Location, roommate compatibility, and place for personal belongings are important considerations for helping the client feel "at home." Changes are often met with resistance and can result in emotional upset and decline in physical condition. Note: Persons with severe behavioral problems or cognitive dysfunctions may require a private room.
Determine client's usual schedule and incorporate into facility routine as much as possible.	Consistency provides reassurance and may lessen confusion and enhance cooperation.
Determine avocation and hobbies client previously pursued. Incorporate activities, if appropriate, into present program.	Encourages involvement in facility activities and helps to stimulate client mentally and physically to improve overall condition and sense of well-being/belonging. Activities need to be personally meaningful for the client to derive the most enjoyment from them, such as talking or Braille books for the blind and closed-caption TV broadcasts for the deaf or hearing impaired.
Note behavior, presence of suspiciousness or paranoia, irritability, and defensiveness. Compare to SO's description of client's customary responses.	Increased stress, physical discomfort, and fatigue may temporarily exacerbate mental deterioration and cognitive decline and further impair communication and social accessibility. This represents a catastrophic episode that can escalate into a panic state and violence.
Be aware of escalating anxiety and presence of delirium. Look for possible causes.	Common causes of delirium include drug toxicity, electrolyte imbalances, withdrawal from alcohol and other drugs, pain, and trauma—especially hip fractures and advanced disease resulting in organ failure.

#### **Collaborative**

Refer to social service or other appropriate agency for assistance. Have case manager or social worker discuss ramifications of Medicare and/or Medicaid if client is eligible for these resources.

Client may not be aware of the resources available, and sources of support can assist with adjustment in new situation.

## NURSING DIAGNOSIS: **Grieving**

### **May Be Related To**

Loss of significant object (e.g., processes of body, job, status, home, possessions)

### **Possibly Evidenced By**

Psychological distress; suffering; despair  
Alterations in activity level; disturbed sleep pattern

### **Desired Outcomes/Evaluation Criteria—Client Will**

#### **Grief Resolution NOC**

Identify and express feelings appropriately.  
Progress through the grieving process.  
Enjoy the present and plan for the future one day at a time.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Grief Work Facilitation NIC</b> <i>Independent</i> Assess emotional state. Note cultural beliefs and expectations.	Anxiety and depression are common reactions to changes and losses associated with long-term illness or debilitating condition. In addition, changes in neurotransmitter levels, such as increased monoamine oxidase (MAO) and serotonin levels with decreased norepinephrine, may potentiate depression in elderly clients. Personal expectations may affect response to change.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Make time to listen to the client. Encourage free expression of hopeless feelings and desire to die.	Allowing these feelings to be expressed, rather than denying or ignoring them, provides a sounding board for the client to hear and reflect on own thoughts, start to deal with the feelings, and consider alternatives.
Assess suicidal potential.	May be related to physical disease, social isolation, and grief. Note: Statistics show that suicide is the eighth leading cause of death among older adults, and elderly males (age 75 and older) are disproportionately more likely than women to die by suicide (CDC, 2012c).
Involve SOs in discussions and activities to the level of their willingness.	When SOs are involved, there is more potential for successful problem-solving. Note: SO may not be available or may choose not to be involved.
Provide liberal touching and hugs as individually accepted.	Conveys sense of concern and closeness to reduce feelings of isolation and enhance sense of self-worth. Note: Touch may be viewed as a threat by some clients and escalate feelings of anger or fear.
Identify spiritual concerns. Discuss available resources and encourage participation in religious activities, as appropriate.	Search for meaning is common to those facing changes in life. Participation in religious or spiritual activities can provide sense of direction and peace of mind.
Assist with planning for specifics as necessary, including advance directives to determine code status, living will wishes, making of will, and funeral arrangements, if appropriate.	Having these issues resolved can help client and SO deal with the grieving process and may provide peace of mind.
<b>Collaborative</b> Refer to other resources as indicated, such as a spiritual advisor, parish nurse, case manager, or social worker.	May need further assistance to resolve some issues.

## NURSING DIAGNOSIS: **impaired Memory**

### May Be Related To

Hypoxia; anemia; decrease in cardiac output  
Neurological disturbances

### Possibly Evidenced By

Inability to recall events or factual information; forgetfulness  
Inability to recall if a behavior was performed  
Inability to learn new information

### Desired Outcomes/Evaluation Criteria—Client Will

#### Cognition NOC

Maintain usual cognitive orientation.  
Demonstrate appropriate information processing.  
Engage in effective decision making.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Cognitive Stimulation NIC</b> <i>Independent</i> Allow adequate time for client to respond to questions or comments and to make decisions.	Reaction time may be slowed with aging due to changes in metabolism and cerebral blood flow or with brain injuries and some neuromuscular conditions.
Discuss happenings of the past. Place familiar objects in room. Encourage the display of photographs and photo albums and frequent visits from SO and friends.	Events of the past may be more readily recalled by the elderly client because long-term memory usually remains intact. Reminiscence or life review and companionship are beneficial to clients.

(continues on page 902)

**ACTIONS/INTERVENTIONS (continued)**

Note presence of short-term memory loss, and provide with such aids as calendars, clocks, room signs, and pictures.

Evaluate individual stress level and deal with it appropriately

Assess physical status and psychiatric symptoms, especially in presence of recent change in mentation or development of confusion. Institute interventions appropriate to findings.

Reorient to person, place, and time, as appropriate.

Have client repeat verbal or written instructions, when indicated.

Note cyclic changes in mentation or behavior, such as evening confusion, picking at bedclothes, pacing, shouting or angry outbursts, or wandering aimlessly.

Involve in regular exercise, activity, and diversional programs.

Schedule at least one rest period per day.

Provide brighter lighting in room and common areas by midafternoon (e.g., 3 p.m.) or earlier on cloudy or winter days.

Turn off lights at bedtime. Provide night lights where appropriate.

Support client's involvement in own care. Provide opportunity for choices on a daily basis.

**Collaborative**

Review results of laboratory and diagnostic tests, such as electrolytes, thyroid studies, or full drug screen and computed tomography (CT) scan.

Administer medications as indicated, such as donepezil (Aricept), rivastigmine (Exelon), galantamine (Razadyne), and memantine (Namenda).

**RATIONALE (continued)**

Short-term memory loss presents a challenge for nursing care, especially if the client cannot remember such things as how to use the call bell or how to get to the bathroom. This problem is not in client's control but may be less frustrating if simple reminders are used to assist in providing continual reorientation. It may be helpful for older person and his or her family to know that short-term memory loss is common and is not necessarily a sign of "senility."

Stress level may be greatly increased because of recent losses, such as poor health, death of spouse or companion, or loss of home. In addition, some conflicts that occur with age come from previously unresolved problems that may need to be dealt with now.

Not all mental changes are the result of aging, and it is important to rule out physical causes before accepting these as unchangeable. Possibilities include pain that is often unreported and underestimated, metabolic imbalances, adverse toxic medication levels, drug-induced side effects (e.g., anti-parkinsonian agents, tricyclic antidepressants), or the result of infectious, cardiac, or respiratory disorders (Amella, 2004).

Helps client maintain focus.

Verifies hearing and ability to read and comprehend.

"Sundowners syndrome" may occur in response to visual and/or hearing deficits enhanced by declining light or an accumulation of all the sensory stimulation during the day, fatigue, inflexible institution schedules, peak-and-trough drug levels, dehydration, and electrolyte imbalances.

Promotes release of endorphins, enhancing sense of well-being, and can improve thinking abilities.

Prevents fatigue; enhances general well-being.

Maximizes visual perception; may limit evening confusion.

Reinforces "sleep time" while meeting safety needs.

Choice is a necessary component in everyday life. Cognitively impaired clients may respond with aggressive behavior as they lose control in their lives.

Aids in establishing cause of changes in mentation and determining treatment options.

Aricept, Exelon, and Razadyne are cholinesterase inhibitors used to treat mild to moderate dementia, whereas Namenda, which regulates glutamine activation, is prescribed for the treatment of moderate to severe dementia (National Institute on Aging [NIA], 2018). (Refer to CP: Dementia of the Alzheimer's Type; Vascular Dementia; Lewy Body Disease; Frontotemporal Dementia.)

**NURSING DIAGNOSIS:** **compromised family Coping****May Be Related To**

Prolonged disease that exhausts supportive capacity of support person  
Insufficient reciprocal support  
Coexisting situations affecting the significant person

**Possibly Evidenced By**

Support person reports preoccupation with personal reactions (e.g., fear, anticipatory grief, guilt, anxiety) to client's need  
Assistive behaviors by support person produce unsatisfactory results  
Support person withdraws from client  
Protective behavior by support person incongruent with client's abilities

**Desired Outcomes/Evaluation Criteria—Family Will****Family Coping NOC**

Identify resources within themselves to deal with the situation.  
Interact appropriately with the client and staff, providing support and assistance, as indicated.  
Verbalize knowledge and understanding of situation.  
Participate in planning for discharge, as appropriate.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Family Support NIC</b>	
<i>Independent</i>	
Introduce staff and provide SO with information about facility and care. Be available for questions. Provide tour of facility.	Helpful to establish beginning relationships. Offers opportunities for enhancing feelings of involvement.
Determine involvement and availability of family and SO.	Clarifies expectations and abilities and identifies needs.
Encourage SO participation in care at level of desire and capability and within limits of safety. Include in social events and celebrations.	Helps family to feel at ease and allows them to feel supportive and a part of the client's life.
Accept choices of SO/family regarding level of involvement in care.	Families may choose to ignore client or may project feelings of guilt regarding placing client in facility by criticizing staff. Note: Feelings of dissatisfaction with the staff may be transferred back to the client.
Evaluate SO's and caregiver's level of stress and coping abilities, especially before planning for discharge.	Caring for and about client with chronic or debilitating conditions places a heavy strain on SO. Recognizing own strengths and areas for improvement provides opportunity for personal growth, enhancing potential for success if client returns home.
Support the caregiver with attention, compassion, time, respect, honesty, advocacy, and understanding.	Nursing interventions need to prepare the caregivers for the challenges they face and meet their needs for compassion and caring.
Identify availability and use of community support systems.	Helps determine areas of need and provides information regarding additional resources to enhance coping.
Be aware of staff's own feelings of anger and frustration about client's and SO's choices and goals that differ from those of staff, and deal with them appropriately.	Group care conferences or individual counseling may be helpful in problem-solving and providing effective care.
<i>Collaborative</i>	
Inform SO of services available to them such as meal tickets, family cooking time or celebrations, group care conference, visiting nurse, caseworker, and other social services.	Promotes feeling of involvement; eases transition in adjustment to client's admission to home care or facility care.
Advise caregivers of resources available, such as Eldercare Locator, Seniornet, Today's Caregiver, and Caregiver Network, Inc.	Helps nurses, clients, and caregivers feel supported and able to provide more skillful care.
Refer SO and caregivers to stress management classes, as indicated.	Although support groups may be very helpful, learning stress management techniques may be more effective in strengthening individual coping as the focus is on the SO rather than the SO-client relationship.

## NURSING DIAGNOSIS: risk for Poisoning [drug toxicity]

### Possibly Evidenced By

[Reduced metabolism; impaired circulation; chronic diseases, organ involvement]  
[Use of multiple prescribed and/or over-the-counter (OTC) drugs]

### Desired Outcomes/Evaluation Criteria—Client Will

#### Risk Control: Drug Use NOC

Maintain prescribed drug regimen free of untoward side effects.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Medication Management NIC</b> <i>Independent</i> Review client's drug regimen on routine basis. Refer to physician for assessment of medications that could be reduced in dose or discontinued.	Reduces risk of client taking too many medications at once (polypharmacy), with attendant problems. Note: Studies support that older adults are more prone to adverse drug reactions (ADRs) and drug-drug interactions due to physiological changes and multiple comorbidities. These reactions are compounded by polypharmacy (Ziere et al, 2006).
Determine allergies, medication, and other drug use history.	Helps avoid repetition or creation of problems.
Review resources such as drug manuals or pharmacist for information about toxic symptoms and side effects. List drug actions and interactions and idiosyncrasies, such as medications that are given with or without foods, as well as those that should not be crushed.	Provides information about drugs being taken and identifies possible interactions. Toxicity can be increased in the debilitated and older client with symptoms not as apparent.
Discuss self-administration of, or access to, OTC products.	Limits interference with prescribed regimen, desired drug action, and organ function. May prevent inadvertent overdosing or toxic reactions. Note: Appropriate use of OTC products kept at bedside or via free access at nurses' station fosters independence and enhances sense of control and self-esteem.
Identify swallowing problems or reluctance to take tablets or capsules.	May not be able to or want to take medication.
Give pills in a spoonful of soft foods, such as applesauce or ice cream, or use liquid form of medication if available.	Ensures proper dosage if client is unable, or does not like, to swallow pills.
Open capsules or crush tablets only when appropriate.	Should not be done unless absolutely necessary because this may alter absorption of medications; for example, enteric-coated tablets may be absorbed in the stomach when crushed, instead of in the intestines.
Make sure client swallows medication.	Ensures effective therapeutic use of medication and prevents pill hoarding.
Observe for changes in condition or behavior.	Behavior may be only indication of drug toxicity, and early identification of problems provides for appropriate intervention. Note: Elderly individuals have increased sensitivity to anticholinergic effects of medications; therefore, use of anticholinergics, anti-parkinsonian agents, benzodiazepines, central nervous system (CNS) depressants, and tricyclic antidepressants may cause delirium or confusion.
Use discretion in the administration of sedatives.	A quiet place where the client can pace or be secluded may be more helpful. If client is destructive or excessively disruptive, pharmacological or mechanical control measures may be required. Convenience of the staff is never a reason for sedating client; however, client safety and rights of other clients need to be taken into consideration.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<b>Collaborative</b> Review drug regimen routinely with physician and pharmacist.	Provides opportunity to alter therapy by reducing dosage or discontinue medications as client's needs and organ functions change, affecting drug absorption, distribution, and renal clearance (Amella, 2004).
Obtain serum drug levels, as indicated.	Determines therapeutic or toxic levels.

### NURSING DIAGNOSIS: impaired verbal Communication

#### May Be Related To

Central nervous system impairment (e.g., Parkinson's disease, Alzheimer's disease)  
Physical barrier (e.g., laryngectomy or tracheostomy)  
Decreased circulation to brain (e.g., stroke, traumatic brain injury)

#### Possibly Evidenced By

Difficulty expressing thoughts verbally (e.g., aphasia, dysphasia)  
Difficulty forming words or sentences (e.g., aphonia, dysarthria)  
Difficulty comprehending or maintaining communication  
Partial/total visual or hearing deficit

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Communication NOC

Establish method of communication by which needs can be expressed.  
Demonstrate congruent verbal and nonverbal communication.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Communication Enhancement: Speech Deficit NIC</b>	
<b>Independent</b>	
Assess reason for lack of communication, including CNS and neuromuscular functioning, gag and swallow reflexes, hearing, and teeth and mouth problems.	Identification of the problem is essential to appropriate intervention. Sometimes clients do not want to talk, may think they talk when they do not, may expect others to know what they want, or may not be able to comprehend or be understood.
Determine whether client is bilingual and what language is primary.	With declining cerebral function or diminished thought processes and increased level of stress, client may mix languages or revert to original language.
Investigate how SO communicates with the client.	Provides opportunity to develop or continue effective communication patterns that have already been established.
Assess client knowledge base and level of comprehension. Treat the client as an adult, avoiding pity and impatience.	Knowing how much to expect of the client can help to avoid frustration and unreasonable demands for performance. However, having an expectation that the client will understand may help raise level of performance.
Establish therapeutic nurse-client relationship through active-listening, being available for problem-solving.	Demonstrates caring about the client as a person.
Make client aware of presence when entering the room by speaking, turning a light off and on, or touching client, as appropriate.	Getting clients' attention is the first step in communication.
Make eye contact, place self at or below client's level, and speak face to face. Encourage client to wear glasses as appropriate.	Conveys interest and promotes contact. Necessary for clients with hearing deficit. Note: When personal protective equipment worn, use special face mask that allows for visualization of mouth.
Speak slowly and distinctly, using simple sentences and yes-or-no questions. Avoid speaking loudly or shouting. Supplement with written communication when possible or needed. Allow sufficient time for reply; remain relaxed with client.	Assists in comprehension and overall communication. Client may respond poorly to high-pitched sounds; shouting also obscures consonants and amplifies vowels.

(continues on page 906)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Use other creative measures to assist in communication, such as picture chart or alphabet board, sign language, or lip reading, when appropriate.	Many options are available, depending on individual situation. Note: Sign language also may be used effectively with other than hearing-impaired individuals.
<b>Communication Enhancement: Hearing Deficit NIC</b>	
Check ears for excess cerumen.	Hardened earwax may decrease hearing acuity and cause tinnitus.
Ascertain if client has or uses hearing aid.	Client may have, but not use, a hearing aid because it may not fit well or it may need batteries.
Be aware that behavioral problems may be associated with hearing loss.	Anger, explosive temper outbursts, frustration, embarrassment, depression, withdrawal, and paranoia may be attempts to deal with communication problems.
<b>Collaborative</b>	
Refer to speech therapists, ear-nose-throat physician, or for audiology, as needed.	Determines extent of hearing loss and whether a hearing aid is appropriate. May be helpful to a client and staff in improving communication. Note: Some sources believe 90% of the clients in extended-care facilities have some degree of hearing loss because this is a common age change. Hearing aids are most effective with conductive losses and may help with sensorineural losses.

## NURSING DIAGNOSIS: disturbed Sleep Pattern

### May Be Related To

Insufficient privacy; disruption caused by sleep partner/roommate  
Ambient temperature; noise; interruptions (facility routines); unfamiliar setting

### Possibly Evidenced By

Alteration in normal sleep pattern  
Feeling unrested; dissatisfaction with sleep  
Difficulty in daily functioning

### Desired Outcomes/Evaluation Criteria—Client Will

#### Sleep NOC

Report improvement in sleep or rest pattern.  
Verbalize increased sense of well-being and feeling rested.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Sleep Enhancement NIC</b>	
<b>Independent</b>	
Ascertain usual sleep habits and changes that are occurring.	Determines need for action and helps identify appropriate interventions.
Provide comfortable bedding and some of own possessions, such as a pillow or an afghan.	Increases comfort for sleep; provides physiological and psychological support.
Establish new sleep routine incorporating old pattern and new environment.	When new routine contains as many aspects of old habits as possible, stress and related anxiety may be reduced, enhancing sleep.
Match with roommate who has similar sleep patterns and nocturnal needs.	Decreases likelihood that “night owl” roommate may delay client’s falling asleep or create interruptions that cause awakening.
Encourage some light physical activity during the day. Make sure client stops activity several hours before bedtime, as individually appropriate.	Daytime activity can help client expend energy and be ready for nighttime sleep; however, continuation of activity close to bedtime may act as a stimulant, delaying sleep.
Promote bedtime comfort regimens such as warm bath, massage, a glass of warm milk, or small amount wine or brandy at bedtime.	Promotes a relaxing, soothing effect. Note: Milk has soporific qualities, enhancing synthesis of serotonin, a neurotransmitter that helps client fall asleep faster and sleep longer.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Instruct in relaxation measures.	Helps induce sleep.
Reduce noise and light.	Provides atmosphere conducive to sleep.
Encourage position of comfort and assist in turning, if needed.	Repositioning reduces pressure on tissues, enhances muscle relaxation, and promotes rest.
Lower bed and position one side against wall when possible. Avoid use of side rails.	May have fear of falling because of change in size and height of bed. Note: Side rails place client at risk for falling when climbing over rails or for possible entrapment.
Avoid or limit interruptions such as awakening for medications or therapies.	Uninterrupted sleep is more restful, and client may be unable to return to sleep when wakened.
<b>Collaborative</b>	
Administer sedatives and hypnotics with caution, as indicated.	May be given to help client sleep or rest during transition period from home to new setting. Note: Avoid habitual use because these drugs decrease rapid eye movement (REM) sleep time.
Provide analgesic medications at bedtime as appropriate.	Perception of pain may be increased during hours of sleep when client is not engaged in daily activities/distraction behaviors.

### NURSING DIAGNOSIS: **risk for imbalanced Nutrition: less than body requirements/Overweight**

#### Possibly Evidenced By

Inability to ingest food (e.g., impaired dentition, inability to feed self effectively)  
 Biological factors (dulling of senses of smell and taste); insufficient interest in food  
 Food intake less than recommended daily allowances  
 Consumption of sugar-sweetened beverages, frequent snacking, portion size larger than recommended  
 Average daily physical activity less than recommended for gender/age

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Nutritional Status **NOC**

Maintain normal weight or progress toward weight goal with normalization of laboratory values and be free of signs of malnutrition and obesity.  
 Demonstrate eating patterns or behaviors to maintain appropriate weight.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Nutrition Management <b>NIC</b></b>	
<b>Independent</b>	
Perform initial nutritional assessment—admission height, weight, and body mass index (BMI); ability to feed self, chew, and swallow; and eating preferences/cultural or religious beliefs.	Provides baseline evaluation to help determine dietary needs and formulate dietary plan incorporating personal preferences (Henkel, 2004).
Evaluate activity pattern.	Extremes of exercise, such as sedentary life or continuous pacing, affect caloric needs.
Incorporate favorite foods and maintain as near-normal food consistency as possible, such as soft or finely ground food with gravy or liquid added. Avoid pureed or baby food whenever possible.	Aids in maintaining intake, especially when mouth and dental problems exist. Baby food is often unpalatable and can decrease appetite and lower self-esteem.
Encourage the use of spices, other than sodium, to client's personal taste.	Reduction in number and acuity of taste buds results in food tasting bland and decreases enjoyment of food and desire to eat.
Provide small, frequent feedings, as indicated.	Decreased gastric motility causes client to feel full and reduces intake.
Serve hot foods hot and cold foods cold.	Foods served at the proper temperature are more palatable, and enjoyment may increase appetite.

(continues on page 908)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Promote a pleasant environment for eating in dining room or with company, if possible.	Eating is, in part, a social event and appetite can improve with increased socialization.
Have healthy snack foods, such as cheese, crackers, soup, and fruit available on a 24-hour basis.	Helps meet individual needs and enhances intake within caloric recommendations.
Plan for social events and provide for snacks even when working to reduce total calories.	Eating is part of socialization, and being able to respond to body's needs enhances sense of control and willingness to participate in dietary program.
Weigh on a regular basis—preferably, same time of day and in similar clothing.	Monitors nutritional state and effectiveness of interventions.
Assess causes of weight loss or gain, such as dysphagia due to decreased saliva production, neurogenic or psychogenic disturbances, tumors, muscular dysfunction, altered senses of smell and taste, or dysfunctional eating patterns related to depression or dementia.	Aids in adjusting plan of care and choice of interventions. Note: In elderly clients, saliva secretion may be decreased and taste buds may be atrophied with reduced sensitivity to sweet and salt.
Review medication regimen for potential effects on food intake.	Drug side effects can impact client's intake; for example, corticosteroids may increase intake; angiotensin-converting enzyme (ACE) inhibitors and antihistamines cause change in taste; antidepressants, NSAIDs, and ferrous sulfate can decrease appetite or cause dysphagia; NSAIDs, antibiotics, digoxin, opiates, and chemotherapeutic agents can cause gastrointestinal (GI) distress, nausea, constipation, or mucositis (Henkel, 2004).
Check state of client's dental health periodically, including fit and condition of dentures, if present.	Oral infections and dental problems, shrinking gums, reaction of client's oral mucous membranes and saliva (associated with some medications or treatments), loss of teeth or ill-fitting dentures can all decrease client's ability to chew.
Monitor total caloric intake, as indicated.	If dietary plan is ineffective in meeting individual goals, calorie count or food diary may help identify problem areas.
Observe condition of skin; note muscle wasting; brittle nails; dry, lifeless hair; and signs of poor healing.	Reflects lack of adequate nutrition.
Encourage exercise and activity program within individual ability.	Promotes sense of well-being and may improve appetite.
<b>Collaborative</b>	
Consult with dietitian.	Aids in establishing specific nutritional program to meet individual client needs.
Provide balanced diet with individually appropriate protein, complex carbohydrates, and calories or as indicated for client's chronic condition/disease state: for example, Mediterranean diet (MeDi) for general well-being and brain health, DASH diet (Dietary Approaches to Stop Hypertension), carbohydrate counting for diabetes, or gluten-free for celiac disease.	Adjustments may be needed to deal with the body's decreased ability to process protein, as well as decreased metabolic rate and levels of activity. Note: Reduced production of salivary ptyalin inhibits digestion of complex carbohydrates in elderly individuals, affecting dietary plan. In addition, delayed insulin release by the pancreas and reduced peripheral sensitivity to insulin decrease glucose tolerance.
Include supplements between meals, as indicated.	May be useful in meeting daily requirements, especially when additional calories/protein required for healing.
Administer vitamin and mineral supplements, as appropriate.	With age, renal and other regulatory systems cannot compensate as well for errors in intake. Mineral requirements change as hormone levels, metabolism, and GI function change. In addition, absorption can be impaired by medication use and chronic illness.
Refer to speech therapist for swallowing evaluation, as indicated.	Information useful in determining diet type or consistency, need for special exercises to strengthen muscles for swallowing, and/or inclusion in a restorative dining program (Henkel, 2004).
Refer for dental care routinely and as needed.	Maintenance of oral and dental health with good dentition can enhance intake.

**NURSING DIAGNOSIS:** **Self-Care deficit: [specify]****May Be Related To**

Alteration in cognitive functioning; perceptual impairment; decreased motivation  
 Neuromuscular or musculoskeletal impairment; weakness  
 Pain, discomfort  
 Fatigue

**Possibly Evidenced By**

Inability to perform ADLs

**Desired Outcomes/Evaluation Criteria—Client Will****Self-Care Status NOC**

Perform self-care activities within level of own ability.  
 Demonstrate techniques or lifestyle changes to meet own needs.  
 Use resources effectively.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Self-Care Assistance NIC</b>	
<i>Independent</i>	
Determine current capabilities (using 0 to 4 scale) and barriers to participation in self-care.	Comprehensive functional assessment includes independent performance of basic ADLs, social activities, sensory abilities, cognition, and ability to ambulate.
Involve client in formulation of plan of care at level of ability.	Enhances sense of control and aids in cooperation and maintenance of independence.
Encourage self-care. Work within present abilities; do not pressure client, but encourage client to reach beyond current capabilities. Provide adequate time for client to complete tasks. Have expectation of improvement and assist as needed.	Doing for oneself enhances feeling of self-worth. Failure can produce discouragement and depression.
Provide and promote privacy, including during bathing or showering.	Modesty may lead to reluctance to participate in care or perform activities in the presence of others.
Use specialized equipment as needed, such as tub transfer seat, grab bars, or raised toilet seat.	Enhances ability to move and perform activities safely.
Give tub bath, using walk-in tub or two-person or mechanical lift if necessary. Use shower chair and spray attachment, as appropriate. Avoid chilling.	Provides safety for those who cannot get into the tub alone. Shower may be more feasible for some clients, though it may be less beneficial or desirable to the client. Elderly or debilitated clients are more prone to chilling.
Shampoo and style hair, as needed. Provide or assist with manicure	Aids in maintaining appearance. Shampooing may be required more or less frequently than bathing schedule.
Encourage use of barber or beauty salon if client is able.	Enhances self-image and self-esteem, preserving dignity of the client.
Acquire clothing with modified fasteners, as indicated.	Use of Velcro instead of buttons or shoelaces can facilitate process of dressing, undressing, and toileting.
Encourage and assist with routine mouth and teeth care daily. Promote, or provide, denture care on a regular basis—cleaning, disinfecting, storage, repair, and use of dental adhesive. Use alternate oral hygiene measures as indicated, such as suction toothbrush, backward-bent toothbrush, chlorhexidine and fluoride mouth rinses, and regular suctioning.	Reduces risk of gum disease and tooth loss, enhances oral health, and promotes proper fitting and use of dentures.
<i>Collaborative</i>	
Consult with physical and/or occupational therapists and rehabilitation specialist.	Useful in establishing exercise and activity program, identifying assistive devices to meet individual needs and safety concerns, and facilitating independence.

## NURSING DIAGNOSIS: risk for impaired Skin Integrity

### Possibly Evidenced By

Mechanical factors (e.g., shearing forces, pressure, restraint)  
Impaired circulation, alteration in sensation  
Moisture (bladder or bowel incontinence)  
Inadequate nutrition (e.g., obesity, emaciation); skeletal prominence  
Extremes of age

### Desired Outcomes/Evaluation Criteria—Client Will

#### Risk Control NOC

Maintain intact skin.  
Identify individual risk factors.  
Demonstrate behaviors or techniques to prevent skin breakdown or facilitate healing.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Skin Surveillance NIC</b> <i>Independent</i> Assess for presence of conditions that may impact skin health.	Client's age and general health can impact skin health; however, other conditions may have more impact (e.g., older client who is smoking, or presence of diabetes, impaired kidney function, vascular insufficiency, incontinence, high risk for falls).
Inspect skin, tissues, and mucous membranes routinely. Observe for dry skin, rashes, evidence of pruritus (e.g., redness, scratches), any type of lesion, skin tears.	Provides opportunity for early intervention in high-risk population, which has less elastic and more fragile skin and tissues.
Anticipate and use preventive measures in clients who are at risk for skin breakdown, such as anyone who is thin, obese, aging, or debilitated; receiving steroid therapy.	Decubitus ulcers/pressure injuries are difficult to heal, and prevention is the best treatment.
Assess nutritional status and initiate corrective measures, as indicated. Provide balanced diet with adequate protein, vitamins, and minerals.	A positive nitrogen balance and improved nutritional state can help prevent skin breakdown and promote wound healing. Note: May need additional calories and protein if draining wound is present.
Encourage adequate fluid intake, especially in presence of cognitive impairment or dementia.	Prevention of dehydration is necessary to maintain circulating volume and tissue perfusion, moist mucous membranes, and good skin turgor to reduce risk of tissue breakdown.
Maintain skin hygiene, using mild, nondetergent soap (e.g., Dove), drying gently and thoroughly, and lubricating.	A daily bath is usually not necessary in elderly clients because there is atrophy of sebaceous and sweat glands, and bathing may create dry skin problems. However, as epidermis thins with age, cleansing and use of moisturizing agents (containing occlusive ingredients [e.g., Vaseline, lanolin], humectants [e.g., glycerin, sorbitol], and emollients) are needed to keep skin soft, smooth, and pliable and to protect susceptible skin from breakdown (Haroun, 2003).
Change position frequently in bed and chair. Recommend 10 minutes of exercise each hour and/or perform passive ROM.	Improves circulation, muscle tone, and joint motion and promotes client participation.
Use a rotation schedule in turning client. Use draw or turn sheet. Pay close attention to client's comfort level.	Allows for longer periods free of pressure; prevents shearing or tearing motions that can damage fragile tissues. Note: Use of prone position depends on client tolerance and should be maintained for only a short time.
Keep sheets and bedclothes clean, dry, and free from wrinkles, crumbs, and other irritating material.	Avoids friction or abrasion injury of skin.
Use elbow and heel protectors and foam, water, or gel pads for positioning in bed and when up in chair. Avoid use of plastic sheet protectors or incontinent pads.	Reduces risk of tissue abrasions and decreases pressure that can impair cellular blood flow. Promotes circulation of air along skin surface to dissipate heat and moisture. Plastic can actually trap heat and moisture against fragile tissues, increasing risk of tissue irritation and breakdown.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Provide for safety during ambulation, using appropriate adaptive devices, such as a walker or cane.	Loss of muscle strength and flexibility and physical disease process or debilitation may result in impaired coordination.
Limit exposure to temperature extremes and use of heating pad or ice pack.	Decreased sensitivity to pain, heat, or cold increases risk of tissue trauma.
Examine feet and nails routinely and provide foot and nail care as indicated:	Foot problems are common among clients who are elderly, diabetic, bedfast, and/or debilitated.
Keep nails cut short and smooth.	Jagged, rough nails can cause tissue damage and infection.
Use lotion or softening cream on feet.	Prevents drying or cracking of skin; promotes maintenance of healthy skin.
Check for fissures between toes, swab with hydrogen peroxide or dust with antiseptic powder, and place a wisp of cotton between the toes.	Prevents spread of infection and/or tissue injury.
Rub feet with witch hazel or a mentholated preparation and have client wear lightweight cotton socks.	Even though rash may not be present, burning and itching may be a problem. Note: Witch hazel may be contraindicated if skin is dry.
Inspect bony prominences, skin surface and folds routinely, especially when incontinence pad or pants are used. Increase preventive measures when reddened areas are noticed.	Skin breakdown can occur quickly with potential for infection and necrosis, possibly involving muscle and bone. There is increased risk of redness and irritation around legs due to elastic bands in adult incontinence pads or pants.
Continue regimen for redness and irritation when break in skin occurs.	Aggressive measures are important because pressure injury can develop in a matter of a few hours.
Observe for pressure injury/incontinence dermatitis development, and treat immediately according to protocol.	Timely intervention may prevent extensive damage.
<b>Collaborative</b>	
Provide waterbed, alternating-pressure, egg-crate, or gel mattress and pad for chair.	Provides protection and improved circulation by decreasing amount of pressure on tissues.
Monitor Hgb and Hct and blood glucose levels.	Anemia, dehydration, and elevated glucose levels are factors in skin breakdown and can impair healing.
Refer to podiatrist, as indicated.	May need professional care for such problems as ingrown toenails, corns, bony changes, and skin or tissue ulceration.
Assist with topical applications, such as hydrogel dressings, skin barrier dressings (Duoderm, Op-Site), collagenase therapy, absorbable gelatin sponges (Gelfoam), and aerosol sprays per protocol.	Although there are differing opinions about the efficacy of these agents, individual or combination use may enhance healing.
Administer nutritional supplements and vitamins, as indicated.	Aids in healing and cellular regeneration.
Prepare for skin grafting. (Refer to CP: Wound Care: Complicated or Chronic; Burns, ND: Impaired Skin/Tissue Integrity.)	May be required to close large ulcers/wounds.

### NURSING DIAGNOSIS: risk for impaired urinary Elimination

#### Possibly Evidenced By

Multiple causality (e.g., changes in fluid or nutritional pattern; perceptual or cognitive impairment)  
Urinary tract infection

#### Outcomes/Evaluation Criteria—Client Will

##### Urinary Elimination NOC

Maintain or regain effective pattern of elimination.  
Initiate necessary lifestyle changes.  
Participate in treatment regimen to correct or control situation, such as bladder training program or use of indwelling catheter.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Elimination Management NIC</b>	
<b>Independent</b>	
Monitor voiding pattern. Identify possible reasons for changes, such as disorientation, neuromuscular impairment, and psychotropic medications.	This information is essential to plan for care and influences choice of individual interventions. Nocturia, frequency, and urgency are common because bladder capacity and/or tone are affected. Bladder pelvic muscles and sphincter tone may also be affected. Note: Urinary incontinence occurs more frequently in older adults but is not considered a normal part of aging (Dowling-Castronovo & Bradway, 2012).
Palpate bladder. Observe for “overflow” voiding and determine frequency and timing of dribbling or voiding.	Bladder distention indicates urinary retention, which may cause incontinence and infection.
Promote fluid intake of 2000 to 3000 mL/d within cardiac tolerance; include fruit juices, especially cranberry juice. Schedule fluid intake times appropriately.	Maintains adequate hydration and promotes kidney function (Dowling-Castronovo & Bradway, 2012). Acid-ash juices act as an internal pH acidifier, retarding bacterial growth. Note: Client may decrease fluid intake in an attempt to control incontinence and become dehydrated. Instead, fluids may be scheduled to decrease frequency of incontinence, such as limiting fluids after 6 p.m. to reduce need to void during the night.
Institute bladder program, including scheduled voiding times and Kegel’s exercises, involving client and staff in a positive manner.	Regular toileting times may help control incontinence. Program is more apt to be successful when positive attitudes and cooperation are present.
Assist client to sit upright on bedside commode, or bedpan, if not able to use toilet.	Provides functional position for voiding.
Provide, or encourage, perineal care daily and as needed.	Reduces risk of contamination and ascending infection.
Use adult incontinence pads or pants during day if needed based on individual type and amount of incontinence. Keep client clean and dry. Provide frequent skin care.	When training is unsuccessful, this is the preferred method of management (Dowling-Castronovo, & Bradway, 2012). Note: Avoiding use of incontinence pads during night exposes skin to air, reducing risk of irritation.
Avoid verbal or nonverbal signs of rejection, disgust, or disapproval over failures.	Expressions of disapproval lower self-esteem and are not helpful to a successful program.
Provide regular catheter care with soap and water, keep collecting bag below level of bladder, and maintain patency of system when indwelling catheter is present.	Reduces risk of ascending infection and/or minimizes reflux (Cravens & Zweig, 2000; Umscheid et al, 2009).
<b>Collaborative</b>	
Administer medications as indicated, such as the following:	
Oxybutynin chloride (Ditropan) and tolterodine tartrate (Detro)l	Promotes bladder sphincter control.
Vitamin C and methenamine mandelate (Mandelamine)	Bladder pH acidifiers retard bacterial growth (Cravens & Zweig, 2000).
Maintain condom or indwelling catheter, or provide intermittent catheterization, if needed, using aseptic technique.	Catheterization for maintenance of continence should be avoided if at all possible, unless needed during healing of sacral or perineal wounds or for client with prolonged immobilization (e.g., spinal cord injury) or to improve comfort at end of life (Umscheid et al, 2009). Note: A single catheter insertion may lead to bacteriuria in up to 20% of elderly clients, and “chronic indwelling catheterization is not a substitute for good nursing care in the management of incontinence” (Cravens & Zweig, 2000).

#### NURSING DIAGNOSIS: **risk for Constipation/Diarrhea**

##### Possibly Evidenced By

Inadequate toileting habits  
Insufficient fluid/fiber intake; poor eating habits  
Decrease in gastrointestinal motility

**NURSING DIAGNOSIS:** **risk for Constipation/Diarrhea** (continued)

Mental confusion  
Prostate enlargement  
Adverse effects of pharmaceutical agents; treatment regimen  
Gastrointestinal inflammation/infection  
Enteral feedings

**Desired Outcomes/Evaluation Criteria—Client Will****Bowel Elimination NOC**

Establish or maintain normal pattern of bowel functioning.  
Demonstrate changes in lifestyle as necessitated by risk or contributing factors.  
Participate in bowel program as able.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Bowel Management NIC</b>	
<i>Independent</i>	
Review medical, surgical, and social history to identify conditions commonly associated with elimination difficulties.	Elimination problems may be multifactorial, and include (1) physical conditions of the gut (e.g., diverticulitis, obstructions, anal fissures); (2) limited physical activity; (3) chronic pain and use of opioid analgesics; (4) neurological disorders (e.g., stroke); (5) poor eating habits, poor diet, food intolerances, malnutrition; (6) use of multiple medications, reaction to medication (e.g., diarrhea caused by antibiotic); (7) age and developmental issues; (8) cognitive decline or dementia with failure to attend to elimination needs; and (9) emotional/psychological issues, such as depression, distress over loss of privacy, and inability to adjust to new surroundings and routines.
Ascertain usual bowel pattern and aids used, including previous long-term laxative use. Compare with current routine.	Determines extent of problem and indicates type of interventions required. Many clients may already be laxative dependent, and it is important to reestablish as near-normal functioning as possible.
Assess reasons for elimination problems; rule out medical causes such as hemorrhoids, drug effect, impaction, infection, bowel obstruction, and cancer.	Identification and treatment of underlying medical condition is necessary to achieve optimal bowel function.
Determine presence of food and/or drug sensitivities.	May contribute to diarrhea.
Institute individualized program of exercise, rest, diet, and elimination.	Depends on the needs of the client. Loss of muscular tone reduces peristalsis or may impair control of rectal sphincter.
Provide diet high in bulk in the form of whole-grain cereals, breads, and fresh fruits—especially prunes and plums.	Improves stool consistency and promotes evacuation.
Encourage increased fluid intake.	Promotes normal stool consistency.
Avoid foods that precipitate diarrhea, limit caffeine and high-fiber foods, avoid milk and fruits, or restrict solid food intake as indicated.	Allows for bowel rest and reduces intestinal workload.
Use adult incontinence pads or pants, if needed. Keep client clean and dry. Provide frequent perineal care. Apply skin protective ointment to anal area.	Prevents skin breakdown.
Keep air freshener in room, at bedside, or in bathroom, as needed.	Limits noxious odors and may help reduce client embarrassment and concern.
Give emotional support to client. Avoid “blaming” talk or actions if incontinence occurs.	Decreases feelings of frustration and embarrassment that can diminish self-esteem.
<i>Collaborative</i>	
Administer medications, as indicated, for example:	If nonpharmacologic treatments are inadequate in managing constipation, laxatives may be added to the treatment regimen (Gallagher, 2008).

(continues on page 914)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Bulk-forming laxatives, (e.g., psyllium seed [Metamucil], methylcellulose [Citrucel]), osmotic laxatives (e.g., low-dose polyethylene glycol [Miralax] and saline laxatives [Ceo-Two, Fleet Enema, Milk of Magnesia])	These agents absorb water, adding to the size of the fecal mass.
Stimulant laxatives (e.g., senna [Ex-Lax, Fletchers Castoria, Senokot]; bisacodyl [Correctol, Dulcolax])	These agents aren't absorbed in the intestine; instead, they pull water into the fecal mass to create more watery stool.
Stool softeners or surfactants (e.g., docusate [Colase, Surfak])	These agents irritate the bowel to increase peristalsis.
Miscellaneous agents (e.g., mineral oil)	These agents cause more water and fat to be absorbed into the stool.
Loperamide (Imodium), atropine/diphenoxylate (Lomotil)	These agents act by lubricating the stool and colon mucosa.
Antibiotic agents	May be needed on a short-term basis for persistent diarrhea to decrease gastrointestinal motility and fluid loss. While diarrhea can be associated with antibiotic use, they may be indicated to treat severe infections (e.g., <i>Shigella</i> or <i>C. difficile</i> ).
Adjust rate/strength of enteral feeding or change formula as indicated.	First option for diarrhea associated with enteral feeding.

### NURSING DIAGNOSIS: impaired physical Mobility

#### May Be Related To

Decrease in endurance, physical deconditioning  
 Decrease in muscle mass/control; joint stiffness; musculoskeletal impairment  
 Pain  
 Alteration in cognitive functioning

#### Possibly Evidenced By

Discomfort; decrease in range of motion  
 Alteration in gait; postural instability  
 Slowed movement

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Mobility NOC

Maintain or increase strength and function of affected body parts.  
 Verbalize willingness to, and participate in, desired activities.  
 Demonstrate techniques or behaviors that enable continuation or resumption of activities.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Environmental Management NIC</b>	
<b>Independent</b>	
Determine functional ability using a scale of 0 to 4 and reasons for impairment.	Identifies need for and degree of intervention required.
Note emotional and behavioral responses to altered ability.	Physical changes and loss of independence often create feelings of anxiety, anger, frustration, and depression that may be manifested as reluctance to engage in activity.
Plan activities and visits with adequate rest periods as necessary.	Can limit or prevent fatigue; conserve energy for continued participation.
Encourage participation in self-care, occupational or recreational activities.	Promotes independence and self-esteem; may enhance willingness to participate.
Provide chairs with firm, high seats and lifting chairs, when indicated.	Facilitates rising from seated position.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<b>Fall Prevention NIC</b> Perform initial and ongoing fall-risk assessment, including fall history, gait and balance assessment, cognition, use of mobility adjuncts, and environmental conditions.	Approximately 50 fall-risk assessment tools exist based on client situation and setting. Information can help determine client's potential for falling and identify which risk factors can be modified, such as medications, uncorrected sensory impairments, or poorly fitting shoes (Lunsford & Wilson, 2015).
Assist with transfers and ambulation if indicated; show client and SO ways to move safely. Use gait belt for assisted transfers.	Prevents accidental falls and injury, especially in the client with altered gait, generalized weakness, orthostatic hypotension, fatigue, and vision disturbances. Note: The highest incidence of falls occurs during transfers (Lunsford & Wilson, 2015).
Obtain supportive shoes and well-fitting, nonskid slippers.	Assists client to walk with a firm step, maintains sense of balance, and prevents slipping (Quigley, 2015).
Remove clutter, wires or cords, scatter rugs, and extraneous furniture from pathways. Keep floors dry.	Reduces risk of falling and injuring self.
Encourage use of hand rails in hallway, stairwells, and bathrooms. Keep bed height in low position except during transfers, provide floor mats, use bed/chair alarms.	Promotes independence in mobility; reduces risk of falls (Quigley, 2015).
Review safe use of mobility aids and adjunctive devices such as walker, braces, and prosthetics.	Facilitates activity and reduces risk of injury.
Provide for environmental changes to meet visual deficiencies:	Prevents accidents and reduces sense of sensory deprivation. If client is visually impaired, may need assistance and ongoing orientation to surroundings.
Keep areas well lighted. Accompany and keep close to client when in unfamiliar areas.	Provides for safety and psychological comfort.
Avoid use of physical restraints.	Studies show that older adults who are restrained, particularly when visually or cognitively impaired, are more likely to experience a fall than those who are not restrained.
Speak to client when entering the room, and let client know when leaving.	Special actions help client who cannot see to know when someone is there.
Encourage client with glasses or contacts to wear them. Be sure glasses are kept clean. Determine reason if glasses are not being worn.	Optimal visual acuity facilitates participation in activities and reduces risk of falls and injury. Client may not be wearing glasses because they need adjustment or change in correction.
<b>Collaborative</b> Arrange for regular eye examinations.	Identifies development or progression of vision problem such as myopia, hyperopia, presbyopia, astigmatism, cataract, glaucoma, tunnel vision, loss of peripheral fields, and blindness and specific options for care.
Consult with physical and occupational therapists and rehabilitation specialist.	Useful in creating individual exercise and activity program and identifying adjunctive aids and injury prevention devices (e.g., low-low beds, hip protectors, helmets, or protective caps) (Hester, 2015). Note: Even in the elderly population, inclusion of moderate weightlifting in the exercise program can improve and maintain the cardiovascular system, decrease obesity and blood pressure, and improve bone density, balance, and muscle tone and strength.

**NURSING DIAGNOSIS: chronic Pain****May Be Related To**

Injury agent (e.g., arthritis, cancer); chronic musculoskeletal condition; nerve compression; ischemic condition  
Age >50 years

(continues on page 916)

**NURSING DIAGNOSIS:** **chronic Pain** (continued)**Possibly Evidenced By**

Self-report of intensity/pain characteristics using standardized pain scale/instrument; self-focused  
Alteration in sleep pattern, ability to continue previous activities

**Desired Outcomes/Evaluation Criteria—Client Will****Pain Level NOC**

Verbalize/demonstrate relief or reduction of pain to manageable level.

**Pain Control NOC**

Engage in behavioral modifications and appropriate use of therapeutic interventions.  
Verbalize enhanced enjoyment of life.

**ACTIONS/INTERVENTIONS****RATIONALE****Pain Management: Chronic NIC****Independent**

Evaluate client's pattern of coping and locus of control.

Passive/avoidant behavioral pattern or lack of active engagement in self-management of activities can contribute to diminished activity and perpetuation of chronic pain. Individuals with external locus of control may take little or no responsibility for pain management.

Determine relevant cultural and spirituality factors affecting pain response.

Pain is accepted and expressed in different ways. Some may magnify symptoms to convince others of reality of pain or believe that suffering in silence helps atone for past wrongdoing.

Evaluate pain behavior, noting past and current pain experience, using pain rating scale (e.g., 0–10 scale or similar tool) or standardized behavior checklist for nonverbal clients, and including functional effects and psychological factors.

Pathophysiology of chronic pain is multifactorial. Effects on lifestyle can include depressed mood, fatigue, weight changes, sleep disturbances, decreased activity, withdrawal.

Provide nonpharmacological methods of pain control considering techniques that may or not been successful in the past.

Engaging in techniques such as progressive muscle relaxation, chair yoga, meditation, visualization or guided imagery, biofeedback, heat or cold application can enhance comfort and decrease need for analgesia.

Encourage participation in mix of activities and stimuli, such as music, news program, educational presentations, crafts, and social interactions, as appropriate.

Offering different activities helps client to try out new ideas and develop new interests providing diversion from focus on pain.

Provide change of scenery when possible, alter personal environment, encourage participation in facility activities, off-site outings, and family events.

Stimulates energy and provides new outlook for client.

**Collaborative**  
Assist in treatment for underlying cause of pain. (Refer to specific care plan.)

Pain management options can vary based on specific condition such as arthritis, multiple sclerosis, herniated disc, peripheral neuropathy of diabetes mellitus, cancer.

Administer medications as indicated such as NSAIDs, opioids, tranquilizers.

Medications may need to be scheduled around the clock, doses titrated up or down, and dose maximized to optimize pain control while managing side effects.

Refer to physical/occupational therapist.

Can design exercise programs, identify assistive devices to enhance mobility.

**NURSING DIAGNOSIS:** **risk for Sexual Dysfunction****Possibly Evidenced By**

Alteration in body function (e.g., disease process, medications, surgery)  
Absence of privacy and/or significant other

**NURSING DIAGNOSIS:** **risk for Sexual Dysfunction** (continued)**Desired Outcomes/Evaluation Criteria—Client Will****Sexual Functioning NOC**

Verbalize knowledge and understanding of sexual limitations, difficulties, or changes that have occurred.

Demonstrate improved communication and relationship skills.

Identify appropriate options to meet needs.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Sexual Counseling NIC</b>	
<i>Independent</i>	
Note client's and SO's cues regarding sexuality.	May be concerned that condition or environmental restrictions may interfere with sexual function or ability but is afraid to ask directly.
Determine cultural and religious values and conflicts or other factors that may be present.	Affects client's perception of existing problems and response of others—family, staff, and other residents. Provides starting point for discussion and problem-solving.
Assess developmental and lifestyle issues.	Factors such as menopause and aging, adolescence, and young adulthood need to be taken into consideration with regard to sexual concerns about illness and long-term care.
Provide atmosphere in which discussion of sexuality is permitted and encouraged.	When concerns are identified and discussed, problem-solving can begin.
Provide privacy for client and SO.	Demonstrates acceptance of need for intimacy and provides opportunity to continue previous patterns of interaction as much as possible.
<i>Collaborative</i>	
Refer to sex counselor or therapist and family therapy when indicated.	May require additional assistance for resolution of issues.

**NURSING DIAGNOSIS:** **readiness for enhanced Health Management****Possibly Evidenced By**

Expresses desire to enhance management of illness/symptoms, risk factors

Expresses desire to enhance management of prescribed regimen

Expresses desire to enhance choices of daily living for meeting goals

**Desired Outcomes/Evaluation Criteria—Client/Caregiver Will****Participation in Health Care Decisions NOC**

Verbalize understanding of factors contributing to current situation.

Adopt lifestyle changes supporting individual healthcare goals.

Assume responsibility for own healthcare needs when possible.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Health Coaching NIC</b>	
<i>Independent</i>	
Assess level of adaptive behavior, knowledge, and skills about health maintenance, environment, and safety.	Identifies areas of concern or need and aids in choice of interventions.
Provide information about individual healthcare needs.	Provides knowledge base and encourages participation in decision making.
Develop plan with client and SO for self-care incorporating existing disabilities and adapting and organizing care.	Assists client and caregiver to maintain and manage desired level of independence when possible.
Maintain adequate hydration and balanced diet with sufficient protein intake.	Promotes general well-being and aids in disease prevention.

(continues on page 918)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Schedule adequate rest with progressive activity program.	Prevents fatigue and enhances general well-being.
Promote good handwashing and personal hygiene. Use aseptic techniques as necessary.	Prevents contamination or cross-contamination, reducing risk of illness or infection.
Protect from exposure to infections and avoid extremes of temperature. Recommend the wearing of masks, monitor staff and visitors, and provide other interventions, as indicated.	With age, immune-protective responses slow down and physiological reactions to temperature extremes may be impaired. As organ function decreases, especially the thymus gland, and natural antibodies decline, clients are at increased risk for infection. Staff and/or visitors with colds or other infections may expose client to these illnesses. Note: Nursing home-acquired pneumonia (NHAP) is a common cause of infection in chronic care facilities and is a significant cause of mortality (Cunha, 2013).
Encourage cessation of smoking.	Smokers are prone to bronchitis and ineffective clearing of secretions.
Encourage reporting of signs and symptoms as they occur.	Provides opportunity for early recognition of developing complications and timely intervention to prevent serious illness.
<b>Health System Guidance NIC</b>	
Note client's previous use of professional services, and continue as appropriate. Include in choice of new health-care providers as able.	Preserves continuity and promotes independence in meeting own healthcare needs.
Observe for and monitor changes in vital signs such as temperature elevation.	Early identification of onset of illness allows for timely intervention and may prevent serious complications. Note: Elderly persons often display subnormal temperatures, so presence of a low-grade fever may be of serious concern.
<b>Collaborative</b>	
Identify resources for, or administer medications, as indicated, for example:	
Immunizations, such as <i>Haemophilus influenzae</i> (flu) and pneumonia	Reduces risk of acquiring contagious, potentially life-threatening diseases.
Antibiotics	May be used prophylactically, depending on individual disease process or risk factors, and to treat infections.
Schedule preventive and routine healthcare appointments based on individual needs with cardiologist, podiatrist, ophthalmologist, or dentist, etc.	Promotes optimal recovery and maintenance of health.
Prepare for discharge or transfer to independent care setting as appropriate.	For some clients, stabilization of chronic conditions, improved nutrition, and medication management may allow movement to lower level of care with adequate family/community support.
Refer to support services as indicated, such as home health care agency, durable medical equipment company, Senior Resources, social services, national hospice organization, Alzheimer's Disease and Related Disorders Association, American Association of Retired Persons (AARP), Center for Health Care Ethics, Choice in Dying, American Bar Association, Commission on Legal Problems of the Elderly, Internet resources, and Adult Protective Services.	Many community resources are available, and often untapped, to make life and care of the individual easier at a lower level of care.

#### POTENTIAL CONSIDERATIONS following discharge from care facility.

Refer to plan of care for diagnosis that required admission.

# ALCOHOL: ACUTE WITHDRAWAL

## I. Pathophysiology (McKeown & West, 2017)

- a. Alcohol intoxication and withdrawal—complex mechanism
- b. Most clinical effects explained by the interaction of ethanol with various neurotransmitters and neuropeptides in the brain
- c. Resulting changes in the inhibitory and excitatory neurotransmitters disrupt the neurochemical balance in the brain, causing symptoms of withdrawal if alcohol is suddenly stopped or decreased after extended usage (Burton, 2010; Donnelly et al, 2012).

## II. Stages of Alcohol Withdrawal (McKeown & West, 2017)

- a. Stage I: autonomic hyperactivity
- b. Stage II: hallucinations
- c. Stage III: neuronal excitation
- d. Stage IV: delirium tremens (DTs)

## III. Etiology

- a. Individual's desire to repeatedly reach a state of feeling high; numb, negative feelings
- b. Associated with serious mental health disorders—anxiety, mood disorders, or major depression
- c. Personality traits—dependency more common in isolation, loneliness, shyness, depression, dependency, hostile and self-destructive impulsivity, and sexual immaturity (Ali et al, 2013)
- d. Environment—frequently come from a broken home and have a disturbed relationship with their parents
- e. Genetics—Incidence of alcoholism is higher in biological children of alcoholics, and some people who become alcoholics are less easily intoxicated, having a higher threshold for central nervous system (CNS) effects.

## IV. Statistics

- a. Morbidity: Approximately 15.1 million adults in the U.S. ages 18 and older had alcohol use disorder (AUD) in 2015

(National Institutes of Health [NIH], n.d.). In 2007, approximately 463,000 hospital discharge episodes in the United States for persons age 15 and older had a principal (first-listed) alcohol-related diagnosis (National Institute on Alcohol Abuse and Alcoholism [NIAAA], 2010); approximately 5% of individuals who have alcohol withdrawal progress to DTs (McKeown & West, 2012).

- b. Mortality: There are approximately 88,000 deaths related to health consequences of alcohol abuse annually (CDC, 2015). This figure includes every type of alcohol-attributable condition or event, including acute causes (e.g., alcohol poisoning, vehicle crashes, fall injuries, homicide) and chronic causes (e.g., alcoholic liver disease, alcoholism, various cancers, pancreatitis, fetal alcohol syndrome). In 2013, over 32,000 liver disease deaths among individuals ages 12 and older involved alcohol (NIH, 2017). Review of death certificates from 2010 to 2012 revealed alcohol poisoning resulted in approximately 22,000 deaths annually (Kanny et al, 2015). Despite appropriate treatment, DTs are reported to have a 5% to 15% mortality rate (McKeown & West, 2012).
- c. Cost: In 2010, the estimated cost of excessive alcohol consumption reached \$249 billion (NIH, 2017). The costs largely resulted from losses in workplace productivity, healthcare expenses for problems caused by excessive drinking, law enforcement and other criminal justice expenses related to excessive alcohol consumption, and motor vehicle crash costs from impaired driving. In 2014, the number of emergency department visits involving alcohol consumption was almost 5 million, resulting in a cost of \$15.3 billion (White, 2018).

## G L O S S A R Y

**Addiction:** Dependence on a substance (such as alcohol or other drugs) or an activity to the point that stopping is very difficult and causes severe physical and mental reactions.

**Alcohol withdrawal syndrome (AWS):** The neurological, psychiatric, and cardiovascular manifestations that result when a person accustomed to consuming large quantities of alcohol suddenly becomes abstinent or reduces usual amount of alcohol intake (Burton, 2010).

**Arcus senilis:** White or gray ring-like opacity of the cornea. **Ataxia:** Gross incoordination of voluntary muscle movement, reflecting loss of proprioception in chronic alcohol abuse.

**Autonomic hyperactivity stage:** Usually occurs within 24 hours of the last drink. Symptoms may be mild, characterized by tremulousness, insomnia, anxiety, diaphoresis, mild tachycardia, and gastrointestinal (GI) upset.

**Binge:** Uninterrupted consumption of a drug for several hours or days.

**Blackout:** Amnesia for events occurring during the period of alcoholic intoxication, even though consciousness is still maintained during that time.

**Delirium tremens (DTs):** Potentially fatal form of alcohol withdrawal characterized by disorientation, confusion, impaired attention, pronounced autonomic hyperactivity, and visual and auditory hallucinations. Usually begins at 48 to 72 hours but can be delayed up to 4 to 5 days. Death is usually due to cardiovascular or respiratory collapse.

**Detoxification:** Process of removing alcohol or other drugs from the body. This is the initial period addicts must go through to become drug-free. Withdrawal symptoms appear early during this process. Depending on the drug, detoxification lasts for a few days to a week or more.

**Gluconeogenesis:** Conversion of glycogen to glucose in the liver.

**Hallucination stage:** Development of false visual (most common), olfactory, or auditory perceptions that have no relation to reality, usually occurring 24 to 36 hours after the cessation of alcohol intake.

**Hepatic encephalopathy:** Condition used to describe the deleterious effects of liver failure on the central nervous system (CNS). Features include confusion ranging to

(continues on page 920)

## G L O S S A R Y (continued)

coma, with alcoholic cirrhosis being the most common cause.	<b>Nystagmus:</b> Unintentional jittery movement of the eyes. Nystagmus usually involves both eyes and is often exaggerated by looking in a particular direction.
<b>Myelosuppression:</b> Decrease in the production by the bone marrow of red blood cells (RBCs), platelets, and some white blood cells (WBCs).	<b>Thrombocytopenia:</b> Low platelet count, which can lead to impaired blood clotting and spontaneous bleeding.
<b>Neuronal excitation stage:</b> Development of autonomic hyperactivity or seizures occurring within 48 hours after cessation of alcohol consumption.	<b>Wernicke's syndrome or Wernicke encephalopathy:</b> Neurological disease characterized by the clinical triad of confusion, inability to coordinate voluntary movement, and eye abnormalities.

## CARE SETTING

Client may be inpatient on a behavioral unit, at a substance abuse rehabilitation facility, or outpatient in community programs. Although clients are not generally admitted to the acute care setting with this diagnosis, withdrawal from alcohol may occur secondarily during hospitalization for other illnesses or conditions (Riddle et al, 2010). An alcohol screening should be done for all hospitalized clients (Burton, 2010; Daly et al, 2009). A short hospital stay may be required during the acute phase because of severity of general condition or comorbidities, or a delayed discharge from acute care can be the result of alcohol withdrawal beginning within 6 to 48 hours of admission.

Respiratory failure/ventilatory assistance, page 187  
Substance use disorders (SUDs), page 929  
Upper gastrointestinal bleeding, page 340

## CLIENT ASSESSMENT DATABASE

Data depend on the duration and extent of use of alcohol, concurrent use of other drugs, degree of organ involvement, and presence of other pathology.

### DIAGNOSTIC DIVISION MAY REPORT

#### ACTIVITY/REST

- Insomnia, difficulty sleeping, not feeling well rested
- Fatigue or weakness

#### CIRCULATION

### MAY EXHIBIT

- Abnormal heart rate or blood pressure (BP) in response to activity
- Tachycardia common during acute withdrawal
- Numerous dysrhythmias may be identified, especially atrial fibrillation
- Hypertension common in early withdrawal stage; may become labile or progress to hypotension
- Peripheral pulses weak, irregular, or rapid

#### EGO INTEGRITY

- Feelings of guilt, shame; defensiveness about drinking
- Denial, rationalization
- Multiple stressors or losses—relationships, employment, finances
- Use of alcohol to deal with life stressors, boredom

- Anxiety, fear
- Irritability
- Antisocial behavior

**MAY REPORT (continued)****ELIMINATION**

- Diarrhea

**FOOD/FLUID**

- Nausea, vomiting; food intolerance
- Anorexia

**NEUROSENSORY**

- “Internal shakes”
- Headache, dizziness, blurred vision
- Blackouts

**PAIN/DISCOMFORT**

- Constant upper abdominal pain and tenderness radiating to the back (pancreatic inflammation)
- Headache (may be “pulsating”)

**RESPIRATION**

- History of smoking
- Chronic respiratory problems

**SAFETY**

- History of recurrent trauma—falls, fractures, lacerations, burns, or motor vehicle crashes
- Violence toward self or others

**MAY EXHIBIT (continued)**

- Bowel sounds varied (may reflect gastric complications such as hemorrhage)

- Gastric distention, ascites, liver and spleen enlargement (seen in cirrhosis)
- Muscle wasting; dry, dull hair; swollen salivary glands; inflamed buccal cavity; capillary fragility (malnutrition)
- Bowel sounds varied (reflecting malnutrition, electrolyte imbalances, general bowel dysfunction)

- Psychopathology—paranoia, schizophrenia, major depression, neurosis (may indicate dual diagnosis)
- Level of consciousness (LOC) and orientation varied—confusion, stupor, hyperactivity, distorted thought processes, slurred, incoherent speech

- Memory loss, confabulation
- Affect/mood/behavior—fearful, anxious, easily startled, inappropriate, silly, euphoric, irritable, physically or verbally abusive, depressed, and/or paranoid

- Hallucinations may be visual, tactile, olfactory, or auditory; for example, client may be picking items out of the air or responding verbally to unseen person or voices

***Eye examination:***

- Nystagmus—associated with cranial nerve palsy
- Pupil constriction (may indicate CNS depression)
- Arcus senilis (normal in aging populations, suggests alcohol-related changes in younger individuals)
- Fine-motor tremors of face, tongue, and hands
- Seizure—grand mal or partial that is usually brief, generalized, tonic-clonic in nature, and without an aura, occurs in a cluster of one to three seizures with a short postictal period; in 20% to 50% of individuals, the seizures progress to DTs (McKeown & West, 2012; Riddle et al, 2010).
- Gait unsteady (ataxia), which may be due to thiamine deficiency or cerebellar degeneration associated with Wernicke’s encephalopathy (Riddle et al, 2010).

- Guarding affected area
- Narrowed focus

- Tachypnea, hyperventilation
- Breath sounds diminished, adventitious sounds (suggests pulmonary complications such as respiratory depression or pneumonia)

- Skin—flushed face and palms of hands; scars, ecchymotic areas; fissures at corners of mouth (vitamin deficiency)
- Fractures healed or new—signs of recent or recurrent trauma
- Temperature elevation, flushing, diaphoresis
- Suicidal ideation; alcohol is a major risk factor in suicide (Ali et al, 2013; Davies, 2012).

(continues on page 922)

## CLIENT ASSESSMENT DATABASE (contd.)

### MAY REPORT (continued)

### MAY EXHIBIT (continued)

#### SEXUALITY

- Loss of sexual desire
- Not achieving sexual satisfaction, or needing alcohol for satisfying sex
- Actual or perceived limitation imposed by disease

#### SOCIAL INTERACTION

- Frequent sick days off from work or school, fighting with others, arrests for disorderly conduct, or motor vehicle violations such as driving under the influence (DUI)
- Denial that alcohol intake has any significant effect on present condition
- Dysfunctional family system of origin (generational involvement), problems in current relationships, often alienated from family when problem is chronic
- Mood changes affecting interactions with others

#### TEACHING/LEARNING

- Family history of alcoholism
- History of alcohol and/or other drug use or abuse, tobacco use
- Ignorance and/or denial of addiction to alcohol, or inability to cut down or stop drinking despite repeated efforts, previous periods of abstinence or withdrawal
- History of daily alcohol use for at least 3 months
- Large amount of alcohol consumed in last 24 to 48 hours (“bingeing”)
- Previous hospitalizations for alcoholism or alcohol-related diseases such as cirrhosis and esophageal varices

#### DISCHARGE PLAN CONSIDERATIONS

- May require assistance to maintain abstinence and begin to participate in rehabilitation program

► Refer to section at end of plan for postdischarge considerations.

## DIAGNOSTIC STUDIES

### TEST

### WHY IT IS DONE

### WHAT IT TELLS ME

#### BLOOD TESTS

- **Blood alcohol level (BAL):** Measures level of alcohol in the blood.

BAL may or may not be severely elevated, depending on amount consumed, time between consumption and testing, and the degree of tolerance, which varies widely. In the absence of elevated alcohol tolerance, blood levels of 100 mg/dL are associated with loss of control of fine motor movements and confusion when faced with tasks requiring thinking; at 200 mg/dL, very slurred speech, ataxia, and lethargy; at 400 mg/dL, coma and respiratory depression; at 500 mg/dL, death is possible due to respiratory arrest, severe hypotension, and aspiration (Balentine, 2018).

WHY IT IS DONE (continued)	WHAT IT TELLS ME (continued)
<ul style="list-style-type: none"> <li><b>Complete blood count (CBC):</b> Battery of screening tests, which typically includes hemoglobin (Hgb); hematocrit (Hct); RBC count, morphology, indices, and distribution width index; platelet count and size; WBC count and differential.</li> </ul>	<p>Blood loss from the GI tract and nutritional deficiencies producing anemia are common in alcohol withdrawal. In addition, alcohol ingestion leads to myelosuppression with a slight reduction in all cell lines. Thrombocytopenia is common. Increased mean corpuscular volume (MCV) suggests anemia based on deficiencies in vitamin B<sub>12</sub> and folate. WBC count may be increased with infection or decreased if client is immunosuppressed.</p>
<ul style="list-style-type: none"> <li><b>Glucose and ketones:</b> Determines ability of liver to manage simple sugars and end products of sugar metabolism.</li> </ul>	<p>Clients with liver disease due to alcoholism have reduced glycogen stores, and alcohol impairs gluconeogenesis. As a consequence, these clients are susceptible to hypoglycemia (McKeown &amp; West, 2012). Ketoacidosis may be present with or without metabolic acidosis. Alcoholic ketoacidosis (AKA) can occur in chronic alcohol abuse with history of recent binge drinking, decreased food intake, and persistent vomiting (Ansstas et al, 2017).</p>
<ul style="list-style-type: none"> <li><b>Electrolytes:</b> Substances that dissociate into ions in solution and acquire the capacity to conduct electricity. Common electrolytes include sodium, potassium, chloride, calcium, and phosphate.</li> </ul>	<p>Alcoholics with liver disease frequently have abnormal sodium serum concentrations, with hyponatremia (low plasma sodium concentration) as the most common alteration. Decreased serum potassium concentration may be associated with respiratory alkalosis, elevated insulin levels, and elevated epinephrine levels resulting from alcohol withdrawal. Client with chronic alcoholism usually has dietary magnesium deficiency and possibly concurrent alcoholic hepatitis. Alcoholic pancreatitis may cause hypocalcemia.</p>
<ul style="list-style-type: none"> <li><b>Liver function tests—lactate dehydrogenase (LDH), alanine aminotransferase (ALT), lipase, and amylase:</b> Determine level of liver and pancreatic dysfunction.</li> </ul>	<p>May be elevated, reflecting liver or pancreatic damage.</p>
<ul style="list-style-type: none"> <li><b>Blood ammonia:</b> Helps evaluate the cause of the change in consciousness.</li> </ul>	<p>Level is elevated if hepatic encephalopathy is present.</p>
<ul style="list-style-type: none"> <li><b>Nutritional tests—albumin or prealbumin, total protein, carbohydrate-deficient transferrin (CDT), iron, vitamins D and B<sub>12</sub>, and folate:</b> Evaluates nutritional status, identifies deficiencies and treatment needs.</li> </ul>	<p>Albumin and total protein may be decreased. CDT, a protein molecule involved in iron transport, is a relatively new test that is sometimes used to help identify chronic, heavy drinking. Vitamin deficiencies are usually present, reflecting malnutrition or malabsorption.</p>
<ul style="list-style-type: none"> <li><b>Drug screens—serum, urine</b></li> </ul>	<p>Identifies drugs being used in conjunction with alcohol that may complicate withdrawal, impact therapy choices.</p>
<h3>OTHER DIAGNOSTIC STUDIES</h3> <ul style="list-style-type: none"> <li><b>Urinalysis:</b> Detects and measures various compounds that pass through the urine.</li> </ul>	<p>Increased WBCs and/or protein may indicate infection; ketones may be related to breakdown of fatty acids in malnutrition (pseudodiabetic condition).</p>
<ul style="list-style-type: none"> <li><b>Chest x-ray:</b> Procedure used to evaluate organs and structures within the chest for symptoms of disease.</li> </ul>	<p>May reveal right lower lobe pneumonia, a common manifestation that may be related to malnutrition, depressed immune system, and aspiration. X-ray may also reveal evidence of chronic lung disorders associated with heavy tobacco use, also common in alcoholics.</p>
<ul style="list-style-type: none"> <li><b>Electrocardiogram (ECG):</b> Record of the electrical activity of the heart.</li> </ul>	<p>Dysrhythmias, cardiomyopathies, and/or ischemia may be present because of direct effect of alcohol on the cardiac muscle and/or conduction system, as well as effects of electrolyte imbalance. The adrenergic storm produced by alcohol withdrawal increases cardiac demand, which may precipitate infarction in susceptible individuals. Atrial fibrillation is the most common cardiac symptom seen in the alcoholic (Burton, 2010).</p>
<ul style="list-style-type: none"> <li><b>Computed tomography (CT) scan of the head:</b> X-ray procedure that uses a computer to produce a detailed picture of a cross section of the body.</li> </ul>	<p>May be obtained in clients with depressed LOC, in those with multiple seizures or signs of head trauma, and in those with failure to respond to treatment. Note: Client with AWS is at risk for intracranial bleeding because of frequent falls, cortical atrophy, and coagulopathy.</p>

(continues on page 924)

WHY IT IS DONE (continued)	WHAT IT TELLS ME (continued)
<ul style="list-style-type: none"> <li>• <b>Clinical Institute Withdrawal Assessment of Alcohol, Revised (CIWA-Ar):</b> Clinical rating tool that provides a numerical rating for 10 factors, including nausea and vomiting, tactile disturbances, tremor, auditory and visual disturbances, sweating, anxiety, headache agitation, and orientation (Donnelly et al, 2012; Hoffman &amp; Weinhouse, 2017).</li> <li>• <b>Addiction severity index (ASI):</b> A 161-item multidimensional clinical and research tool that produces a “problem severity profile” of the client, including chemical, medical, psychological, legal, family and social, and employment and support aspects, indicating areas of treatment needs.</li> </ul>	<p>Provides a clinical quantification of the severity of the alcohol withdrawal syndrome and can be rapidly administered at the bedside. Scores of 9 to 15 points correspond with moderate withdrawal, and scores greater than 15 correspond to severe withdrawal symptoms and increased risk of DTs and seizures.</p> <p>Provides basic diagnostic information on a client prior to, during, and after treatment for substance use-related problems as well as for the assessment of change in client status and treatment outcome.</p>

## NURSING PRIORITIES

1. Maintain physiological stability during acute withdrawal phase.
2. Promote client safety.
3. Provide appropriate referral and follow-up.
4. Encourage and support significant other (SO) involvement in “intervention” or confrontation process.
5. Provide information about condition, prognosis, and treatment needs.

\*\*\*This plan of care is to be used in conjunction with CP: Substance Use Disorders.

## DISCHARGE GOALS

1. Homeostasis achieved.
2. Complications prevented or resolved.
3. Sobriety maintained on a day-to-day basis.
4. Ongoing participation in rehabilitation program or group therapy, such as Alcoholics Anonymous (AA).
5. Condition, prognosis, and therapeutic regimen understood.
6. Plan in place to meet needs after discharge.

## NURSING DIAGNOSIS: Acute Substance Withdrawal Syndrome

### May Be Related To

Developed dependence to alcohol; heavy use of an addictive substance over time  
Sudden cessation of an addictive substance

### Possibly Evidenced By

Anxiety; acute confusion  
Risk for electrolyte imbalance  
Risk for injury

### Desired Outcomes/Evaluation Criteria—Client Will

#### Substance Withdrawal Severity NOC

Demonstrate absence of untoward effects of withdrawal (e.g., seizures, dysrhythmias).  
Experience no physical injury.  
Report absence or reduced frequency of hallucinations.  
Verbalize reduction of fear and anxiety to a manageable level free of emotional outbursts.

#### Alcohol Abuse Cessation Behaviors NOC

Commit to cease alcohol use.  
Engage in counseling/support group.

## ACTIONS/INTERVENTIONS

## RATIONALE

### Substance Use Treatment: Alcohol Withdrawal NIC

#### Independent

Develop a trusting relationship through frequent contact and being honest and nonjudgmental. Project an accepting attitude about alcoholism.

Provides client with a sense of humanness, helping to decrease paranoia and distrust. Client will be able to detect biased or condescending attitude of caregivers.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Inform client about what you plan to do and why. Include client in planning process and provide choices when possible.	Enhances sense of trust, and explanation may increase cooperation and reduce anxiety. Provides sense of control over self in circumstance where loss of control is a significant factor. Note: Feelings of self-worth are intensified when one is treated as a worthwhile person.
Assess LOC, ability to speak, and response to stimuli and commands. Observe for behavioral responses such as hyperactivity, disorientation, confusion, sleeplessness, and irritability.	Speech may be garbled, confused, or slurred. Response to commands may reveal inability to concentrate, impaired judgment, or muscle coordination deficits. Hyperactivity related to CNS disturbances may escalate rapidly. Sleeplessness is common due to loss of sedative effect gained from alcohol usually consumed before bedtime. Sleep deprivation may aggravate disorientation or confusion. Progression of symptoms may indicate impending hallucinations (stage II) or DTs (stage IV).
Determine stage of AWS using CIWA-Ar. Stage I is associated with signs and symptoms of hyperactivity, such as tremors, sleeplessness, nausea, vomiting, diaphoresis, tachycardia, and hypertension; stage II is manifested by increased hyperactivity plus hallucinations and/or seizure activity; stage III symptoms include DTs and extreme autonomic hyperactivity with profound confusion, anxiety, insomnia, and fever.	AWS usually begins 3 to 36 hours after the last drink. Prompt recognition and intervention may halt progression of symptoms and enhance recovery, improving prognosis. In addition, progression of symptoms indicates need for changes in drug therapy and more intense treatment to prevent death. DTs may not present until 2 to 3 days after last alcohol intake, usually lasting 1 to 5 days.
Assist client to identify cause of anxiety. Explain that alcohol withdrawal increases anxiety and uneasiness. Reassess level of anxiety on an ongoing basis.	Persons in acute phase of withdrawal may be unable to identify and/or accept what is happening. Anxiety may be physiologically or environmentally caused. Note: Individuals with alcohol use disorders often also have posttraumatic stress disorder (PTSD) (U.S. Department of Veterans Affairs, 2011).
Encourage SO to stay with client whenever possible.	Promotes recognition of caregivers and a sense of consistency, which may reduce fear.
Note onset of hallucinations and document as auditory, visual, and/or tactile.	Auditory hallucinations are reported to be more frightening and threatening to client. Visual hallucinations occur more at night and often include insects, animals, or faces of friends or enemies. Clients are frequently observed “picking the air.” Yelling may occur if client is calling for help from perceived threat, which is usually seen in stage III of AWS.
Reorient frequently to person, place, time, and surrounding environment, as indicated.	Client may experience periods of confusion, resulting in increased anxiety. May have a calming effect and reduce confusion, prevent or limit misinterpretation of external stimuli.
Provide quiet environment. Speak in calm, quiet voice. Regulate lighting, as indicated. Turn off radio or TV during sleep.	Reduces external stimuli during hyperactive stage. Client may become more delirious when surroundings cannot be seen, but some respond better to quiet, darkened room.
Avoid bedside discussion about client or topics unrelated to the client that do not include the client.	Client may hear and misinterpret conversation, which can aggravate hallucinations.
Provide environmental safety as indicated; for example, place bed in low position, leave doors in full open or closed position, observe frequently, place call light/bell within reach, and remove articles that can harm client.	Client may have distorted sense of reality or be fearful or suicidal, requiring protection from self.
Assist with ambulation and self-care activities, as needed.	Prevents falls, reducing possible injury. May be required when equilibrium and hand-eye coordination problems exist, impacting performance of ADLs.

(continues on page 926)

**ACTIONS/INTERVENTIONS (continued)**

Observe for and document seizure activity. Maintain patent airway. Provide environmental safety such as padded side rails and bed in low position.

Check deep-tendon reflexes (DTRs). Assess gait, if possible.

Palpate upper arm to discern actual withdrawal versus medication-seeking behavior.

**Collaborative**

Monitor laboratory studies such as electrolytes, magnesium levels, liver function studies, ammonia, BUN, glucose, and ABGs.

Administer medications, as indicated, for example:

Benzodiazepines (BZDs), such as chlordiazepoxide (Librium), diazepam (Valium), lorazepam (Ativan), oxazepam (Serax), or clonidine (Catapess)

Barbiturates, such as phenobarbital, or possibly secobarbital (Seconal) or pentobarbital (Nembutal)

Haloperidol (Haldol)

**RATIONALE (continued)**

Generalized tonic-clonic convulsions are most common and may be related to decreased magnesium levels, hypoglycemia, and elevated blood alcohol and usually occur within 12 to 48 hours of last drink. Note: In absence of history of seizures or other pathology causing them (e.g., head trauma), they usually stop spontaneously or with magnesium replacement (Burns et al, 2017; Hoffman & Weinhouse, 2017).

Reflexes may be depressed, absent, or hyperactive.

Peripheral neuropathies are common, especially in malnourished client. Ataxia is associated with Wernicke's syndrome (thiamine deficiency) and cerebellar degeneration. Three ways to assess whether the client is having actual withdrawal tremors are (1) have the client stick out his or her tongue—it will be tremulous; (2) feel the client's upper arm—withdrawal tremors can be felt bone deep; and (3) have the client visually track a pencil—there will be observable nystagmus.

Changes in organ function may precipitate or potentiate sensory-perceptual deficits. Electrolyte imbalance is common. Liver function is often impaired in the chronic alcoholic, and ammonia intoxication can occur if the liver is unable to convert ammonia to urea. Ketoacidosis is sometimes present without glycosuria; however, hyperglycemia or hypoglycemia may occur, suggesting pancreatitis or impaired gluconeogenesis in the liver. Hypoxemia and hypercarbia are common manifestations in chronic alcoholics who are also heavy smokers.

BZDs are commonly used to control neuronal hyperactivity and promote relaxation and sleep because of their minimal respiratory and cardiac depression and anticonvulsant properties. In addition, drugs that have little effect on dreaming may be desired to allow dream recovery or rapid eye movement (REM) rebound to occur, which has previously been suppressed by alcohol use. Studies have also shown that these drugs can prevent progression to more severe states of withdrawal. Intravenous (IV) or oral (PO) administration is preferred route because intramuscular (IM) absorption is unpredictable. Muscle-relaxant qualities are particularly helpful to client in controlling "the shakes," trembling, and ataxic quality of movements. Note: Lorazepam and oxazepam may be preferred in clients with advanced cirrhosis or acute alcoholic hepatitis due to shorter drug half-life and a decrease in effects if oversedation occurs (Hoffman & Weinhouse, 2017).

These drugs are sometimes used with benzodiazepines to treat or prevent alcohol withdrawal seizures but need to be used with caution because they are respiratory depressants and REM sleep cycle inhibitors and may mask hemodynamic signs of withdrawal, which can precede seizures (Hoffman & Weinhouse, 2017).

Occasionally may be used in conjunction with BZDs for clients experiencing agitation and hallucinations, although should be used with caution as it can lower seizure threshold and interfere with heat dissipation (Hoffman & Weinhouse, 2017).

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Thiamine, glucose	Thiamine deficiency may lead to neuritis, Wernicke's syndrome (abnormal gait and paralysis of eye muscles as well as cognitive deficits), and/or Korsakoff's psychosis (Riddle et al, 2010).
Vitamins C and B complex, multivitamins, and Stresstabs	Vitamins may be depleted because of insufficient intake and malabsorption. Vitamin deficiency, especially thiamine, is associated with ataxia, loss of eye movement and pupillary response, palpitations, postural hypotension, and exertional dyspnea.
Magnesium sulfate	Reduces tremors and seizure activity by decreasing neuromuscular excitability. Process wherein SO and family members, supported by staff, provide information about how client's drinking and behavior have affected each one of them; helps client acknowledge that drinking is a problem and has resulted in current situational crisis.
Provide seclusion and restraints as necessary, adhering to facility policy regarding restraints.	Clients with excessive psychomotor activity, severe hallucinations, violent behavior, and/or suicidal gestures may respond better to seclusion. Physical restraints are usually ineffective and add to client's agitation and increase risk of rhabdomyolysis but occasionally may be required to prevent harm to self/others until adequate chemical sedation is achieved (Hoffman & Weinhouse, 2017).
Arrange "intervention" or confrontation in controlled setting when client has recovered sufficiently from withdrawal to address addiction issues.	Client is more likely to contract for treatment while still hurting and experiencing fear and anxiety from last drinking episode. Motivation decreases as well-being increases and person again feels able to control the problem.
Provide consultation or referral to detoxification or crisis center for ongoing treatment program as soon as medically stable (e.g., oriented to reality).	Direct contact with available treatment resources provides realistic picture of help. Decreases time for client to "think about it," change mind, or restructure and strengthen denial systems.

### NURSING DIAGNOSIS: risk for ineffective Breathing Pattern

#### Possibly Evidenced By

Neuromuscular impairment (e.g., direct effect of alcohol toxicity on respiratory center and/or sedative drugs given to decrease alcohol withdrawal symptoms)

Fatigue

[Tracheobronchial obstruction]

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Respiratory Status: Ventilation NOC

Maintain effective breathing pattern with respiratory rate within normal range, lungs clear, and free of cyanosis or other signs and symptoms of hypoxia.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Respiratory Monitoring NIC</b> <i>Independent</i> Monitor respiratory rate, depth, and pattern as indicated. Note periods of apnea and Cheyne-Stokes respirations.	Frequent assessment is important because toxicity levels may change rapidly. Hyperventilation is common during acute withdrawal phase. Kussmaul's respirations are sometimes present because of acidotic state associated with vomiting and malnutrition. However, marked respiratory depression can occur because of CNS depressant effects of alcohol if acute intoxication is present. This may be compounded by drugs used to control AWS.

(continues on page 928)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Auscultate breath sounds. Note presence of adventitious sounds such as rhonchi, wheezes.	Client is at risk for atelectasis related to hypoventilation and pneumonia.
<b>Airway Management NIC</b> Elevate head of bed.	Decreases potential for aspiration; lowers diaphragm, enhancing lung inflation.
Encourage coughing, deep-breathing exercises, and frequent position changes.	Facilitates lung expansion and mobilization of secretions to reduce complications from atelectasis or pneumonia.
Have suction equipment and airway adjuncts available.	Sedative effects of alcohol potentiate risk of aspiration, relaxation of oropharyngeal muscles, and respiratory depression, requiring intervention to prevent respiratory arrest.
<b>Collaborative</b> Administer supplemental oxygen, if necessary.	Hypoxia may occur with respiratory depression and chronic anemia.
Review serial chest x-rays, arterial blood gases (ABGs), or pulse oximetry, as indicated.	Monitors presence of secondary complications, evaluates effectiveness of respiratory effort, and identifies therapy needs. Note: Right lower lobe pneumonia is common in alcohol-debilitated clients and is often due to chronic aspiration. Chronic lung diseases, such as emphysema or bronchitis, are also common.
Transfer to higher level of care/critical care unit as indicated. (Refer to CP: Respiratory Failure/Ventilatory Assistance.)	May require more aggressive pulmonary therapy/mechanical ventilation if unable to maintain adequate oxygenation.

### NURSING DIAGNOSIS: risk for decreased Cardiac Output

#### Possibly Evidenced By

Altered contractility (e.g., direct effect of alcohol on the heart muscle)  
Altered afterload—systemic vascular resistance  
Alteration in heart rate/rhythm

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Circulation Status NOC

Display vital signs within client's normal range; absence, or reduced frequency, of dysrhythmias.  
Demonstrate an increase in activity tolerance.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Hemodynamic Regulation NIC</b> <i>Independent</i> Monitor vital signs frequently during acute withdrawal.	Hypertension frequently occurs in acute withdrawal phase. Extreme hyperexcitability, accompanied by catecholamine release and increased peripheral vascular resistance, raises BP and heart rate; however, BP may become labile and progress to hypotension. Note: Client may have underlying cardiovascular disease, which is compounded by alcohol withdrawal.
Monitor cardiac rate and rhythm. Document irregularities and dysrhythmias.	Long-term alcohol abuse may result in cardiomyopathy and heart failure (HF). Tachycardia is common because of sympathetic response to increased circulating catecholamines. Dysrhythmias may develop with electrolyte imbalance. All of these may have an adverse effect on cardiac output.
Monitor body temperature.	Elevation may occur because of sympathetic stimulation, dehydration, and/or infections, causing vasodilation and compromising venous return and cardiac output.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Monitor intake and output (I&O). Note 24-hour fluid balance.	Preexisting dehydration, vomiting, fever, and diaphoresis may result in decreased circulating volume that can compromise cardiovascular function. Note: Hydration is difficult to assess in the alcoholic client because the usual indicators are not reliable, and overhydration is a risk in the presence of compromised cardiac function.
Be prepared for and assist in cardiopulmonary resuscitation.	Causes of death during acute withdrawal stages include cardiac dysrhythmias, respiratory depression and arrest, oversedation, excessive psychomotor activity, severe dehydration or overhydration, and massive infections. Mortality for DTs ranges from 5% to 15% (Burns et al, 2017).
<b>Collaborative</b>	
Monitor laboratory studies, such as serum electrolyte levels, RBCs, Hgb and Hct, and platelets.	Potassium and magnesium imbalances potentiate risk of cardiac dysrhythmias. Anemia may be present and platelets can be decreased in late-stage alcoholism due to liver dysfunction.
Administer fluids and electrolytes, as indicated, especially potassium (Riddle et al, 2010).	Severe alcohol withdrawal causes the client to be susceptible to excessive fluid losses associated with diuresis, fever, diaphoresis, and vomiting; electrolyte imbalances, especially potassium and magnesium that can result in life-threatening dysrhythmias (Hoffman & Weinhouse, 2017).
Administer medications, as indicated, for example:	
Clonidine (Catapres) or atenolol (Tenormin)	Although the use of benzodiazepines is often sufficient to control hypertension during initial withdrawal from alcohol, some clients may require more specific therapy. Note: Atenolol and other beta-adrenergic blockers may speed up the withdrawal process and eliminate tremors as well as lower the heart rate, BP, and body temperature but are not useful in preventing seizures or DTs (Burns et al, 2017; Hoffman & Weinhouse, 2017).
Consult with medical toxicologist or regional poison control center as needed.	Useful resources for diagnosis and management of acute/critically ill clients (Hoffman & Weinhouse, 2017).

**POTENTIAL CONSIDERATIONS** following acute care (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

Refer to: Substance Use Disorders (SUDs) plan of care and plans of care for any specific underlying medical condition(s).

## SUBSTANCE USE DISORDERS (SUDs)

### I. Pathophysiology

- a. Considered a continuum of phases incorporating a cluster of cognitive, behavioral, and physiological symptoms, including loss of control over use of the substance and a continued use of the substance to reach a state of feeling high despite adverse consequences—effects on all body systems, relationship problems, financial difficulties, self- or other-directed violence, exposure to criminal element and activities, legal consequences.
- b. All commonly abused drugs stimulate the brain's limbic system, elevating dopamine levels and affecting level of alertness, perceptions, emotions, judgment, attention, movement, and sleep (Ali et al, 2013; Crews, 2011).
- c. Prescription drug abuse is the fastest-growing type of drug abuse in the United States, and deaths from prescription drugs are reaching epidemic proportions (Garcia, 2013; Phillips, 2013).
- d. The following is a recently compiled list of commonly misused substances in descending order according to the number of people affected (National Institute on Drug Abuse [NIDA], 2016):
  - i. Alcohol: An estimated 20 million adults in the United States abuse alcohol. **P** More than half of these alcoholics started drinking heavily when they were teenagers (American Academy of Child and Adolescent Psychiatry, 2012).

(continues on page 930)

- ii. Bath salts (synthetic cathinones): new family of drugs containing one or more manmade chemicals related to cathinone, an amphetamine-like stimulant found naturally in the khat plant. **P** Teens and young adults are gravitating to these easy-to-access drugs, as they incorrectly believe them to be legal and harmless (Lohmann, 2012).
- iii. Club drugs: includes methamphetamines (e.g., “speed, crystal, meth, crank”), methamphetamine-derivative methylenedioxymethamphetamine (MDMA, Ecstasy), and other stimulant drugs such as methylphenidate (Ritalin), phencyclidine (PCP), and ketamine (Special K). **P** Club drugs are not only popular in raves (all-night dance parties with loud, pounding music and flashing lights stimulating vigorous dancing) but are often used in other social settings frequented by adolescents and young adults (Dryden-Edwards, 2017).
- iv. Cocaine: The National Survey on Drug Use and Health (NIDA, 2017a and NSDUH, 2015) report that cocaine use has gone down in the last few years. In 2013, the number of current users aged 12 or older was 1.5 million, down from 1.9 million in 2008.
- v. Heroin: In 2011, 4.2 million Americans aged 12 or older had used heroin at least once in their lives. **P** Although heroin abuse has trended downward during the past several years, its prevalence is still higher than in the early 1990s, especially among school-age youth (NIDA, 2013).
- vi. Inhalants: includes volatile solvents (e.g., paint thinner, nail-polish remover), aerosols (e.g., spray paint, hair or deodorant spray), gases (e.g., butane lighters, nitrous oxide [laughing gas]), and hydrocarbons (e.g., fluorinated hydrocarbons, found in whipped cream dispensers called “whippets”). **P** Data from national and state surveys suggest that inhalant abuse is most common among seventh through ninth graders (NIDA for Teens, 2017).
- vii. K2/Spice (also called synthetic marijuana, fake weed, Yucatan Fire, Skunk, Moon Rocks): wide variety of herbal mixtures that produce experiences similar to marijuana. **P** Of the illicit drugs most used by high school seniors, K2 is secondary only to marijuana (NIDA, 2016).
- viii. LSD (acid) and other hallucinogens such as psilocybin (mushrooms, “shrooms”), phencyclidine (PCP): **P** In 2013, the National Survey on Drug Use and Health (NSDUH) stated that approximately 1.3 million persons aged 12 or older reported using hallucinogens (NSDUH, 2014).
- ix. Marijuana (e.g., pot, grass, weed, reefer, mary jane): **P** In 2012, 6.5% of 12th graders reported using marijuana daily, compared to 5.1% in 2007 (NIDA, 2017).
- x. Tobacco (street names for tobacco delivery methods include “smokes, cigs, chew, dip, snuff”): **P** In 2012, smoking was at historically low levels among young people, according to NIDA’s Monitoring the Future study (reported as 4.9% for 8th graders and 17.1% for 12th graders) (NIDA, 2017).
- xi. Prescription drugs: In 2010, the National Institute on Drug Abuse reported that an estimated 52 million people (20% of those aged 12 and older) have used prescription drugs for nonmedical reasons at least once

in their lifetimes. **P** In 2015, it was reported that in the 12 to 17 age group, data on “past-year” of any prescription psychotherapeutic drug, dependence or abuse is higher than in adults. In this age group, females exceed males in the nonmedical use of all psychotherapeutics, including pain relievers, tranquilizers, and stimulants, and are more likely to be dependent on stimulants (National Institutes of Health [NIH], 2015). These include:

1. Opioids, such as fentanyl (Duragesic), hydrocodone (Vicodin), oxycodone (OxyContin, Percocet), oxymorphone (Opana), propoxyphene (Darvon), hydromorphone (Dilaudid), meperidine (Demerol), morphine (Kadian, Avenza), diphenoxylate (Lomotil)
2. Central nervous system (CNS) depressants, such as pentobarbital sodium (Nembutal), diazepam (Valium), alprazolam (Xanax)
3. Stimulants such as dextroamphetamine (Dexedrine), methylphenidate (Ritalin and Concerta), amphetamines (Adderall)

## II. Etiology

- a. No single theory developed to date explains condition.
- b. Multiple predisposing factors implicated in abuse of substances (Claros & Sharma, 2012):
  - i. Biological—genetic predisposition, chronic pain, illness, trauma
  - ii. Biochemical—properties of psychoactive drugs, individual’s higher threshold for central nervous system (CNS) effects
  - iii. Psychological—depression; psychosis (Charles & Weaver, 2010); personality traits including isolation, low self-esteem, passivity, impulsivity, sexual immaturity, lack of emotional intelligence (Claros & Sharma, 2012); comorbidity with schizophrenia in 50% of cases (Bridgeman, 2013)
  - iv. Sociocultural—unstable home environment, disturbed relationship with parental figures, peer or group pressure, conditioning, availability of substance, childhood sexual abuse (Sartor et al, 2013)
- v. Cultural and ethnic influences—attitudes toward alcohol or drug use, expectation that substance can safely relieve distress

## III. Statistics

- a. Morbidity: Excessive alcohol use, either in the form of heavy drinking or binge drinking, occurred in approximately 17% of the U.S. population in 2013, and 6% reported heavy drinking (CDC, 2015). In the 2014 survey by the Substance Abuse and Mental Health Services Administration (SAMHA) published in 2015, illicit drugs with the highest levels of past-year dependence or abuse were marijuana (an estimated 4.2 million people ages 20 or older), pain relievers (1.9 million), and cocaine (1 million). In 2011, there were 5.1 million drug-related emergency department (ED) visits; about one-half (49%) were attributed to drug misuse or abuse. Among visits involving drug misuse or abuse, 1.4 million visits involved pharmaceuticals and 1.3 million involved illicit drugs (Substance Abuse and Mental Health Services Administration [SAMHSA], 2015). Only 11.2% of people who were found to need substance use treatment received such treatment in a specialty facility (Center for Behavioral Health Statistics and Quality [CBHSQ], 2011).

- b. Mortality: More than 64,000 Americans died from drug overdoses in 2016, including illicit drugs and opioids, almost double in a decade, according to a report published by the National Institute on Drug Abuse (NIDA, 2017).
- c. Cost: According to a survey published in 2011 by the U.S. Department of Justice, use of illicit drugs in 2007 (the most recent year for which data were available) cost \$11 billion

for healthcare and more than \$193 billion overall, with the majority share attributable to lost productivity (U.S. Department of Justice [DOJ], 2011). The National Institute on Drug Abuse (NIDA, 2016) report did not have updated data with one exception: that report estimates in 2013 prescription opioid health care costs of \$26 billion with \$78.5 in overall costs.

## G L O S S A R Y

- Addiction:** Chronic relapsing brain disorder characterized by compulsive drug seeking and use and by long-lasting chemical changes in the brain.
- ATOD:** Stands for alcohol, tobacco, and other drug—acronym used for addressing substance use in interviews.
- CAGE Screening tool:** A questionnaire focusing on individual's attempts to Cut down on drinking (or drug use), and Annoyance with criticism from others regarding use, and Guilt about substance use, and using alcohol (or drug) as an Eye opener or to counter negative effects of withdrawal.
- Cognitive-behavioral therapy:** Assists clients to recognize, avoid, and cope with situations in which they are most likely to use substance.
- Compulsive:** Type of behavior a person exhibits that is overpowering, repeated, and, often, irrational.
- Craving:** Powerful desire for a substance that cannot be ignored.
- Detoxification:** Medically supervised treatment for alcohol or drug addiction designed to purge the body of intoxicating or addictive substances.
- Dual diagnosis:** Co-occurring mental illness and substance abuse.
- Enabling:** Doing for the client what he or she needs to do for self—rescuing. Due to shame and fear, significant others (SOs) and family member(s) often allow the drug or alcohol user to continue disruptive, irrational behavior patterns.

**Harm reduction:** Program that accepts the reality of drug use while attempting to reduce its harmful consequences to individuals and society. An example could be a “clean-needle program” for intravenous (IV) drug users.

**Medication-assisted treatment (MAT):** The use of FDA-approved medications with counseling and behavioral therapies to treat SUDs.

**Motivational incentives/contingency management:** Uses positive reinforcement/tangible rewards to encourage abstinence from substance(s).

**Motivational interviewing:** Nonconfrontational approach assisting client to explore internal motivations for client's behavior and feelings of ambivalence and fear of change in an effort to find motivation to make changes and accomplish treatment goals.

**Multidimensional family therapy:** Developed for adolescents and their families to address a range of influences on the client's substance use patterns and which is designed to improve overall family functioning.

**Peer support:** Structured relationship in which people meet to provide or exchange emotional support with others facing similar challenges. Peer-to-peer groups, such as Alcoholics Anonymous (AA), Narcotics Anonymous (NA), Smart Recovery, and online forums.

**Substance use disorder (SUD):** Condition that is used to describe a person dependent on or abusing alcohol and/or drugs, including the nonmedical use of prescription drugs.

## CARE SETTING

Client is treated inpatient on behavioral unit/residential facility or outpatient in a day program or community agency.

## RELATED CONCERNS

Alcohol: acute withdrawal, page 919

Psychosocial aspects of care, page 835

## CLIENT ASSESSMENT DATABASE

Data depend on substances involved, duration of use, and organs affected.

### MAY REPORT

#### ADDITIONAL DATA REQUIREMENTS

- Family issues—discipline, conflict, attitudes
- Peer and individual—the individual's delinquency, perception of risk, friends' attitudes and use of substances
- History of substances used—type used, length of use; method of use (e.g., snorting, smoking, injecting, or swallowing); amount taken each time
- Family history and genetic makeup

### MAY EXHIBIT

- Family issues—communication
- Community—availability of substances, attitudes regarding use
- Work or school—attendance, performance or grades
- Risk-taking behaviors
- Medical and mental health comorbidities

(continues on page 932)

**CLIENT ASSESSMENT DATABASE** (contd.)**MAY REPORT** (continued)**MAY EXHIBIT** (continued)**TEACHING/LEARNING**

- **Discharge plan considerations:** May need assistance with long-range plan for recovery
- Refer to section at end of plan for postdischarge considerations.

**DIAGNOSTIC STUDIES****TEST  
WHY IT IS DONE****WHAT IT TELLS ME****DRUG SCREENS**

- **Drug screens:** Serum, urine, saliva, sweat, and/or hair may be tested.
- **Screening for use or relapse:** Variety of tools may be used, such as Alcohol Use Disorders Identification Test (AUDIT), CAGE survey, Drug Abuse Screening Test (DAST), and brief Michigan Alcoholism Screening Test (MAST).
- **Addiction Severity Index (ASI) assessment tool:** Produces a “problem severity profile” of the client, including chemical, medical, psychological, legal, family and social, and employment and support aspects.
- **Other screening studies (e.g., hepatitis, HIV, tuberculosis [TB], venereal diseases):** Depends on general condition, individual risk factors, and care setting.

Identifies drug(s) being used, including usual drugs of abuse—alcohol, heroin, marijuana, cocaine, and inhalants.

Useful in determining patterns reflecting social, vocational, or family problems associated with alcohol intake or abuse of other drugs. MAST has a geriatric version and P DAST has an adolescent version.

Reveals treatment needs and areas to be addressed.

Reveals organ involvement and presence of comorbidities.

**NURSING PRIORITIES**

1. Provide support for decision to stop substance use and adopt a harm reduction program.
2. Strengthen individual coping skills.
3. Facilitate learning of new ways to reduce anxiety.
4. Promote family involvement in rehabilitation program.
5. Facilitate family growth and development.
6. Provide information about condition, prognosis, and treatment needs.

**DISCHARGE GOALS**

1. Responsibility for own life and behavior assumed.
2. Plan to maintain substance-free life formulated.
3. Family relationships and enabling issues being addressed.
4. Treatment program successfully begun.
5. Condition, prognosis, and therapeutic regimen understood.
6. Plan in place to meet needs after discharge.

**NURSING DIAGNOSIS: ineffective Denial****May Be Related To**

Anxiety; threat of unpleasant reality  
Excessive stress  
Ineffective coping strategies  
Threat of unpleasant reality

**Possibly Evidenced By**

Delay in seeking or refusal of healthcare; minimizes symptoms  
Does not admit impact of condition on life

**NURSING DIAGNOSIS:** **ineffective Denial** (continued)

Use of dismissive comments or gestures when speaking of distressing events  
Does not perceive personal relevance of danger

**Desired Outcomes/Evaluation Criteria—Client Will****Acceptance: Health Status NOC**

Verbalize awareness of relationship of substance use to current situation.  
Engage in therapeutic program.  
Verbalize acceptance of responsibility for own behavior.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Behavior Modification NIC</b> <i>Independent</i>	
<b>P</b> Ask client (including pediatric client) about alcohol, tobacco, and other drug (ATOD) use at each contact.	Although client may deny or minimize actions, healthcare provider can open the door to obtaining help and treatment for client by asking broad questions in initial and subsequent interviews. In 2014, an estimated 14.5 million adults aged 26 or older had SUDs. <b>P</b> Note: An estimated 1.3 million adolescents aged 12 to 17 and 5.7 million young adults aged 18 to 25 also had SUDs in 2014 (Substance Abuse and Mental Health Services Administration [SAMHSA], 2015).
Convey attitude of acceptance, separating individual from unacceptable behavior.	Promotes feelings of dignity and self-worth. Demonstrates caring attitude.
Ascertain reason for beginning abstinence and involvement in therapy.	Provides insight into client's willingness to commit to long-term behavioral change and whether client even believes that he or she can change. Note: Denial is one of the strongest and most resistant manifestations of SUD. The decision to quit is an important step to success in therapy.
Review definition of drug dependence and use with categories of symptoms, including risk factors, patterns of use, impairment caused by use, tolerance to substance.	This information helps client make decisions regarding acceptance of problem and treatment choices. <b>P</b> Note: The risk of becoming a drug abuser involves the relationship among the number and type of risk factors (e.g., deviant attitudes and behaviors) and protective factors (e.g., parental support). Early intervention with risk factors (e.g., aggressive behavior and poor self-control) often has a greater impact than later intervention by changing a child's life path (trajectory) away from problems and toward positive behaviors (Hawkins et al, 2008).
Answer questions honestly and provide factual information. Keep your word when agreements are made.	Creates trust, which is the basis of the therapeutic relationship.
Provide information about addictive use versus experimental, occasional use; biochemical and genetic disorder theory—genetic predisposition, use activated by environment; and compulsive desire.	Progression of use continuum ranges from experimental or recreational to addictive use. Comprehending this process is important in combating denial. Education may relieve client's guilt and blame and may help awareness of recurring addictive characteristics.
Discuss current life situation and impact of substance use.	First step in decreasing use of denial is for client to see the relationship between substance use and personal problems.
Confront and examine denial and rationalization in peer group. Use confrontation with caring attitude.	Because denial is the major defense mechanism in addictive disease, confrontation by peers can help the client accept the reality of adverse consequences of behaviors and that drug use is a major problem. Caring attitude preserves self-concept and helps decrease defensive response.
Provide information regarding effects of addiction on mood and personality.	Individuals often mistake effects of addiction and use this to justify or excuse drug use.

(continues on page 934)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Remain nonjudgmental. Be alert to changes in behavior such as restlessness and increased tension.	Confrontation can lead to increased agitation, which may compromise safety of client and staff.
Provide positive feedback for expressing awareness of denial in self and others.	Necessary to enhance self-esteem and to reinforce insight into behavior.
Maintain firm expectation that client attends recovery support and therapy groups regularly.	Attendance is related to admitting need for help, to working with denial, and for maintaining long-term, substance-free existence.
Encourage and support client's taking responsibility for own recovery, such as development of alternative behaviors to drug urge and use. Assist client to learn own responsibility for recovering.	Denial can be replaced with positive action when client accepts the reality of own responsibility.
Be aware of own enabling behaviors. Understand professional boundaries needed to be therapeutic with client experiencing a SUD (Tsai et al, 2010).	Caregiving lends itself to "taking care" of clients that can backfire in substance abuse treatment.

### NURSING DIAGNOSIS: risk for Acute Substance Withdrawal Syndrome

#### Possibly Evidenced By

Developed dependence to alcohol or other addictive substance  
Heavy use of an addictive substance over time  
Sudden cessation of an addictive substance

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Substance Withdrawal Severity NOC

Display stable vital signs and usual orientation, absence of hallucinations and seizure activity.  
Free of agitation or emotional outbursts.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Substance Use Treatment NIC</b>	
<i>Independent</i>	
Note presence of comorbidities—medical conditions/psychiatric disorders and currently prescribed medications.	Suggests additional monitoring and potential treatment needs.
Assess vital signs (VS) and level of consciousness (LOC) as indicated.	VS and LOC can be labile, based on specific substance(s) and length of time since last used, requiring more in-depth evaluation and medical intervention.
Identify stage of alcohol withdrawal syndrome (AWS) using CIWA-Ar. Stage I is associated with signs and symptoms of hyperactivity, such as tremors, sleeplessness, nausea, vomiting, diaphoresis, tachycardia, and hypertension; stage II is manifested by increased hyperactivity plus hallucinations and/or seizure activity; stage III symptoms include DTs and extreme autonomic hyperactivity with profound confusion, anxiety, insomnia, and fever.	AWS usually begins 3 to 36 hours after the last drink. Prompt recognition and intervention may halt progression of symptoms and enhance recovery, improving prognosis. In addition, progression of symptoms indicates need for changes in drug therapy and more intense treatment with possible transfer to higher level of care (refer to CP: Alcohol: Acute Withdrawal).
Monitor for signs of withdrawal relative to other substance(s) used.	Not all clients will have completed the withdrawal process prior to admission, and symptoms and timing of occurrence depend on type of substance(s) used and last dose. For example: Heroin flu-like symptoms begin within 12 hours of last dose, peaks 24 to 48 hours and lasting a week to up to a few months. Prescription painkillers—opiate flu-like symptoms begin within 8 to 12 hours, peak 12 to 48 hours, and last 5 to 10 days. Cocaine depression and restlessness start within hours of last dose, peak in 7 to 10 days, and last 1 to 10 weeks.

## ACTIONS/INTERVENTIONS (continued)

## RATIONALE (continued)

**Collaborative**

Administer medications, as indicated, for example:

Disulfiram (Antabuse)

Benzodiazepines anxiety and/or seizures begin within 1 to 4 days, peaking in a few days and lasting weeks or (in some cases) months (American Addiction Centers, n.d., 2017). Presence and degree of symptoms may require medical evaluation and support.

Medications can be used to manage withdrawal symptoms, prevent relapse, and treat co-occurring conditions (NIDA, 2016; SAMHSA, 2015). Note: There are no FDA-approved medications for treating cannabis, cocaine, or methamphetamine SUDs and **P** medication-assisted treatments (MAT) are rarely used to treat adolescent alcohol use (NIDA, 2016).

Acamprosate (Campral EC)

This drug can be helpful in maintaining abstinence from alcohol while other therapy is undertaken. By inhibiting alcohol oxidation, the drug leads to an accumulation of acetaldehyde with a highly unpleasant reaction if alcohol is consumed.

Helps prevent relapses in alcoholism by lowering receptors for the excitatory neurotransmitter glutamate. This agent may become drug of choice because it does not make the user sick if alcohol is consumed; it has no sedative, antianxiety, muscle-relaxant, or antidepressant properties and produces no withdrawal symptoms.

Buprenorphine (Buprex, Subutex, Suboxone)

Used in the treatment of opioid addiction. At low doses, it produces sufficient agonist effect to enable opioid-addicted individuals to discontinue the misuse of opioids without experiencing withdrawal symptoms. This drug carries a lower risk of abuse, dependence, and side effects compared to full opioid agonists (Liberto & Fornili, 2013). **P** Note: FDA does not recommend Subutex and Suboxone for use in pediatric clients (NIDA, 2016).

Methadone (Dolophine) and levo-acetylmethadol (LAAM)

Methadone is thought to blunt the craving for or diminish the effects of opioids and is used to assist in withdrawal and long-term maintenance programs. It can allow the individual to maintain daily activities and ultimately withdraw from drug use. LAAM, a long-acting synthetic  $\mu$  agonist, is an effective alternative to methadone maintenance and only has to be taken three times a week. Harm reduction needs to be considered versus the possibility of exchanging one addiction for another (Tetrault & Fiellin, 2012).

Naltrexone (Narcan) and nalmefene (Revex)

Used to suppress craving for opioids and may help prevent relapse in the client abusing alcohol. Current research suggests that naltrexone suppresses urge to continue drinking by interfering with alcohol-induced release of endorphins (Tetrault & Fiellin, 2012). Used in emergency situations to prevent death from overdose. Note: Genetic differences may affect how well the drug works in certain clients (NIDA, 2016).

Monitor results of periodic drug testing as appropriate.

Important to identify that return to substance use or change to another drug results in serious consequences.

## NURSING DIAGNOSIS: **ineffective Coping**

### May Be Related To

Situational/maturational crisis; uncertainty  
Inadequate confidence in ability to deal with a situation  
Ineffective tension release strategies  
Inadequate resources; insufficient social support (created by characteristics of relationships)

### Possibly evidenced by

Substance abuse; risk taking; destructive behavior toward self  
Insufficient problem-solving or problem resolution  
Ineffective coping strategies  
Inability to deal with a situation, ask for help

### Desired Outcomes/Evaluation Criteria—Client Will

#### Substance Addiction Consequences NOC

Identify consequences of using substance as a method of coping.

#### Coping NOC

Identify other ineffective coping behaviors.  
Engage in problem-solving using effective coping skills.  
Initiate necessary lifestyle changes.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Substance Use Treatment NIC</b> <i>Independent</i> Review program rules, philosophy, and expectations.	Having information provides opportunity for client to cooperate and function as a member of the group or milieu, enhancing sense of control and sense of success.
Determine understanding of current situation and previous or other methods of coping with life's problems.	Provides information about degree of denial, acceptance of personal responsibility, and commitment to change; identifies coping skills that may be used in present situation. Note: Adolescents are at high risk for drug abuse due to incomplete brain development, which may lead to poor decision making and risk taking (Winters & Arria, 2011).
Set limits and confront efforts to get caregiver to grant special privileges, making excuses for not following through on agreed-upon behaviors and attempting to continue drug use. Avoid use of labels, such as lying.	Client has learned manipulative behavior throughout life and needs to learn a new way of getting needs met. Following through on consequences of failure to maintain limits can help the client to change ineffective behaviors. Use of labels promotes negative attitudes that can impede therapeutic relationships.
Be aware of staff attitudes, feelings, and enabling behaviors.	Lack of understanding and judgmental or enabling behaviors can result in inaccurate data collection and nontherapeutic approaches.
Encourage verbalization of feelings, fears, and anxiety.	May help client begin to come to terms with long-unresolved issues.
Explore alternative coping strategies.	Client may have little or no knowledge of adaptive responses to stress and needs to learn other options for managing time, feelings, and relationships without drugs.
Assist client to learn and encourage use of relaxation skills, guided imagery, and visualizations.	Helps client relax and develop new ways to deal with stress and to problem-solve.
Structure diversional activity that relates to recovery such as social activity within support group, wherein issues of being chemically free are examined.	Discovery of alternative methods of coping with drug hunger can remind client that addiction is a lifelong process and opportunity for changing patterns is available.
Use peer support to examine ways of coping with drug hunger.	Self-help groups, such as Alcoholics Anonymous (AA), Narcotics Anonymous (NA), and Crystal Methamphetamine Anonymous (CMA), are valuable for learning and promoting abstinence in each member by using understanding and support as well as peer pressure.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Identify possible and actual triggers for relapse. Encourage client to use the acronym HALT—"Am I hungry, angry, lonely, or tired?"	Employment and financial stressors, isolation, unhealthy relationships, being around substance-using friends, hearing certain songs, premenstrual syndrome—the list of possibilities depends on the individual. Being aware of the triggers provides an opportunity to plan for ways to avoid and deal with them.
Encourage involvement in therapeutic writing. Have client begin journaling or writing autobiography.	Therapeutic writing or journaling can enhance participation in treatment; serves as a release for grief, anger, and stress; provides a useful tool for monitoring client's safety; and can be used to evaluate client's progress. Autobiographical activity provides an opportunity for client to remember and identify sequence of events in his or her life that relate to current situation.
Discuss client's plans for living without drugs.	Provides opportunity to develop and refine plans. Devising a comprehensive strategy for avoiding relapses helps client into maintenance phase of behavioral change.
<b>Collaborative</b> Collaborate with counselors and provide consistency in treatment approach.	Individual counseling can promote skill building and adherence to a recovery plan through techniques such as cognitive-behavioral therapy, contingency management, and motivational interviewing/incentives therapies (NIDA, 2016).
Encourage involvement with self-help associations such as AA, NA, or CMA. Facilitate visit by a group member/possible sponsor as appropriate.	Puts client in direct contact with support system necessary for managing sobriety and drug-free life.
Refer to community or social resources such as housing assistance, employment agencies, childcare, food stamps, or alternative schooling.	Dealing with life problems in a proactive way enhances coping abilities, reduces sense of isolation and hopelessness, and decreases risk of relapse.

NURSING DIAGNOSIS:	Powerlessness
<b>May Be Related To</b>	Unsatisfactory interpersonal interactions; insufficient social support; social marginalization Ineffective coping strategies; low self-esteem Complex treatment regimen
<b>Possibly Evidenced By</b>	Insufficient sense of control; shame; depression; alienation Dependency (substance use) Inadequate participation in care
<b>Desired Outcomes/Evaluation Criteria—Client Will</b>	
<b>Health Beliefs: Perceived Threat NOC</b>	Admit inability to control drug habit and surrender to powerlessness over addiction. Verbalize acceptance of need for treatment and awareness that willpower alone cannot control abstinence.
<b>Acceptance: Health Status NOC</b>	Demonstrate active participation in care and treatment program. Regain and maintain healthy state with a drug-free lifestyle.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Self-Responsibility Facilitation NIC</b> <i>Independent</i> Use crisis intervention techniques to initiate behavior changes:	May need to use emergency commitments or other legal holds for the client's safety. Client may be more amenable to acceptance of need for treatment at this time. <i>(continues on page 938)</i>

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Assist client to recognize problem exists. Discuss in a caring, nonjudgmental manner how drug has interfered with life.	In the precontemplation phase, the client has not yet identified that drug use is problematic. While client is hurting, it is easier to admit substance use has created negative consequences.
Involve client in development of treatment plan, using problem-solving process in which client identifies goals for change and agrees to desired outcomes.	During the contemplation phase, the client realizes a problem exists and is thinking about a change of behavior. The client is committed to the outcomes when the decision-making process involves solutions that are promulgated by the individual.
Discuss alternative solutions.	Brainstorming helps creatively identify possibilities and provides sense of control. During the preparation phase, minor action may be taken as individual organizes resources for definitive change.
Assist in selecting most appropriate alternative.	As possibilities are discussed, the most useful solution becomes clear.
Support decision and implementation of selected alternative(s).	Helps the client persevere in process of change. During the action phase, the client engages in a sustained effort to maintain sobriety and mechanisms are put in place to support abstinence.
Explore support in peer group. Encourage sharing about drug hunger, situations that increase the desire to indulge, and ways that substance has influenced life.	Client may need assistance in expressing self, speaking about powerlessness, and admitting need for help in order to face up to problem and begin resolution.
Assist client to learn ways to enhance health and structure healthy diversion from drug use, including maintaining a balanced diet, getting adequate rest, exercise such as walking, slow or long-distance running, and acupuncture, biofeedback, or deep meditative techniques.	Learning to empower self in constructive ways can strengthen ability to continue recovery. These activities help restore natural biochemical balance, aid detoxification, and manage stress, anxiety, and use of free time. These diversions can increase self-confidence, thereby improving self-esteem. Note: Exercise promotes release of endorphins, creating a feeling of well-being.
Provide information regarding understanding of human behavior and interactions with others, such as transactional analysis.	Understanding these concepts can help the client to begin to deal with past problems and losses and prevent repeating ineffective coping behaviors and self-fulfilling prophecies.
Assist client in self-examination of spirituality and faith.	Although not mandatory for recovery, surrendering to and faith in a power greater than oneself has been found to be effective for many individuals in substance recovery; may decrease sense of powerlessness.
Instruct in and role-play assertive communication skills.	Effective in helping refrain from use, to stop contact with users and dealers, to build healthy relationships, and to regain control of own life.
Provide treatment information on an ongoing basis.	Helps client know what to expect and creates opportunity for client to be a part of what is happening and make informed choices about participation and outcomes.
<b>Collaborative</b>	
Refer to, or assist with making contact with, programs for ongoing treatment needs—partial hospitalization drug treatment programs; NA, AA, CMA, or peer support groups.	Continuing treatment is essential to positive outcome. Follow-through may be easier once initial contact has been made.

## NURSING DIAGNOSIS: imbalanced Nutrition: less than body requirements

### May Be Related To

Insufficient dietary intake—psychological, physiological, or insufficient finances

### Possibly Evidenced By

Weight loss; body weight below norm for height and body build

Alteration in taste sensation; food intake less than recommended daily allowance; insufficient interest in food

Insufficient muscle tone; sore buccal cavity

[Laboratory evidence of protein and vitamin deficiencies]

**NURSING DIAGNOSIS:** **imbalanced Nutrition: less than body requirements** (continued)**Desired Outcomes/Evaluation Criteria—Client Will****Nutritional Status NOC**

Demonstrate progressive weight gain toward goal with normalization of laboratory values and absence of signs of malnutrition.

**Knowledge: Treatment Regimen NOC**

Verbalize understanding of effects of substance abuse and reduced dietary intake on nutritional status.

Demonstrate behaviors or lifestyle changes to regain and maintain appropriate weight.

**ACTIONS/INTERVENTIONS****RATIONALE****Nutrition Therapy NIC****Independent**

Assess height, weight, age, body build, strength, and activity and rest levels. Note condition of oral cavity.

Provides information on which to base individual caloric needs and dietary plan. Type of foods may be affected by condition of mucous membranes and teeth.

Take anthropometric measurements, such as midarm muscle circumference, triceps skinfold, and percentage of body fat, when available.

Calculates subcutaneous fat and muscle mass to aid in determining dietary needs.

Note total daily calorie intake. Recommend client maintain a diary of intake, as well as times and patterns of eating.

Information will help identify nutritional deficiencies.

Evaluate energy expenditure (e.g., pacing or sedentary), and establish an individualized exercise program.

Activity level affects nutritional needs. Exercise enhances muscle tone and may stimulate appetite.

Provide opportunity to choose foods and snacks to meet dietary plan.

Enhances sense of control, may promote resolution of nutritional deficiencies, and helps evaluate client's understanding of dietary teaching.

Recommend monitoring weight weekly.

Provides information regarding effectiveness of dietary plan.

**Collaborative**

Consult with dietitian.

Useful in establishing individual dietary needs and plan and provides additional resource for learning.

Review laboratory studies as indicated, such as glucose, serum albumin or prealbumin, and electrolytes.

Identifies anemias, electrolyte imbalances, and other abnormalities that may be present, requiring specific therapy.

Refer for dental consultation as necessary.

Teeth are essential to good nutritional intake, and oral hygiene and dental care are often a neglected area in this population.

**NURSING DIAGNOSIS:** **chronic low Self-Esteem****May Be Related To**

Repeated failures, negative reinforcement

Receiving insufficient affection; inadequate respect from others

Psychiatric disorder

Cultural incongruencies

**Possibly Evidenced By**

Underestimation of ability to deal with situation

Repeatedly unsuccessful in life events

Rejection of positive feedback; exaggerates negative feedback about self

**Overly conforming; passivity****Desired Outcomes/Evaluation Criteria—Client Will****Self-Esteem NOC**

Identify feelings and underlying dynamics for negative perception of self.

Verbalize acceptance of self as is and an increased sense of self-worth.

Set goals and participate in realistic planning for lifestyle changes necessary to live without drugs.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Self-Esteem Enhancement NIC</b>	
<i>Independent</i>	
Provide opportunity for and encourage verbalization and discussion of individual situation.	Client often has difficulty expressing self, even more difficulty accepting the degree of importance substance has assumed in life and its relationship to present situation.
Assess mental status. Note presence of other psychiatric disorders.	Many clients use substances in an attempt to obtain relief from depression or anxiety, which may predate use and/or be the result of substance use. Approximately 60% of substance-dependent clients have underlying psychological problems or a dual diagnosis, and treatment for both is imperative to achieve and maintain abstinence.
Spend time with client. Discuss client's behavior and use of substance in a nonjudgmental way. Note cultural, racial/ethnic, religious, gender issues.	The nurse's presence conveys acceptance of the individual as a worthwhile person. Based on personal issues, client may be dealing with stigma of condition, discrimination, and scarcity of community resources necessitating additional support.
Provide grief counseling, as indicated.	Discussion provides opportunity for insight into the problems substance abuse has created for the client. Life losses secondary to alcohol or other drug use problems need to be addressed to enable client to move forward with rehabilitation.
Provide reinforcement for positive actions and encourage client to accept this input.	Failure and lack of self-esteem have been problems for this client, who needs to learn to accept self as an individual with positive attributes.
Observe family interactions and SO dynamics and level of support.	Substance abuse is a family disease, and how the members act and react to the client's behavior affects the course of the disease and how client sees self. Many unconsciously become "enablers," helping the individual to cover up the consequences of the abuse. (Refer to ND: dysfunctional Family Processes, following.)
Encourage expression of feelings of guilt, shame, and anger.	The client often has lost respect for self and believes that the situation is hopeless. Expression of these feelings helps client begin to accept responsibility for self and take steps to make changes.
Help client acknowledge that substance use is the problem and that problems can be dealt with without the use of drugs. Confront the use of defenses—denial, projection, and rationalization.	When drugs can no longer be blamed for the problems that exist, client can begin to deal with the problems and live without substance use. Confrontation helps client accept the reality of the problems as they exist.
Ask client to list and review past accomplishments and positive happenings.	There are things in everyone's life that have been successful. Often when self-esteem is low, it is difficult to remember these successes or to view them as successes.
Use techniques of role rehearsal.	Assists client to practice developing skills to cope with new role as a person who no longer uses or needs drugs to handle life's problems.
<i>Collaborative</i>	
Involve client in group therapy.	Group sharing helps encourage verbalization because other members of the group are in various stages of abstinence from drugs and can address the client's concerns or denial. The client can gain new skills, hope, and a sense of family or community from group participation.
Engage in motivational enhancement therapy.	Assists individuals with SUDs to build motivation and commit to specific treatment plans and seek recovery.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Formulate plan to treat other mental illness problems.	Clients who seek relief for other mental health problems through drugs will continue to do so once discharged. Both the substance use and the mental health problems need to be treated together to maximize abstinence potential. Treatment may be difficult because of difficulty of taking initiative, thinking realistically, and problem-solving. Behavioral methods seem to be most helpful.
Administer antipsychotic medications, such as quetiapine (Seroquel) or olanzapine (Zyprexa or Zydis), as necessary.	Prolonged or profound psychosis following lysergic acid diethylamide (LSD) or phencyclidine (PCP) use can be treated with these drugs because it is probably the result of an underlying functional psychosis that has now emerged. Methamphetamine psychosis often does not reverse. Note: Avoid the use of phenothiazines because they may decrease seizure threshold and cause hypotension in the presence of LSD or PCP use.
Monitor for diabetes, weight gain, and dyslipidemia.	Atypical antipsychotics (e.g., Zyprexa) are associated with these effects and should be monitored closely for changes in glucose control. Measurement of fasting blood glucose at the beginning of therapy and periodical monitoring during therapy are recommended.

### NURSING DIAGNOSIS: dysfunctional Family Processes

#### May Be Related To

Substance misuse; addictive personality  
Ineffective coping strategies; insufficient problem-solving skills  
Family history of substance misuse, resistance to treatment  
Genetic predisposition to substance misuse

#### Possibly Evidenced By

Feelings: anxiety, anger, shame, embarrassment, emotional isolation, loneliness, vulnerability, repressed emotions  
Roles and responsibilities: disturbance in family dynamics, closed communication system, ineffective communication with partner, change in role function, disruption in family roles, inconsistent parenting  
Behaviors: manipulation, dependency, criticizing, rationalization, denial of problems, enabling maintenance of substance use pattern, refusal to get help, inability to receive help appropriately

#### Desired Outcomes/Evaluation Criteria—Family Will

#### Family Coping NOC

Verbalize understanding of dynamics of enabling behaviors.  
Participate in individual family programs.  
Identify ineffective coping behaviors and consequences.  
Initiate and plan for necessary lifestyle changes.  
Take action to change self-destructive behaviors and alter behaviors that contribute to partner's/SO's addiction.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Substance Use Treatment NIC</b>	
<b>Independent</b>	
Review family history and explore roles of family members, circumstances involving drug use, strengths, and areas for growth.	Determines areas for focus and potential for change.
Explore how the SO has coped with the client's habit—use of denial, repression, rationalization, projection, feelings of hurt, and loneliness.	The person who enables also suffers from the same feelings as the client and uses ineffective methods for dealing with the situation, necessitating help in learning new, more effective coping skills.
Determine understanding of current situation and previous methods of coping with life's problems.	Provides information on which to base present plan of care.

(continues on page 942)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Assess current level of functioning of family members. Determine extent of enabling behaviors being evidenced by family members and explore with each individual and client.	Affects individual's ability to cope with situation. People want to be helpful and do not want to feel powerless to help their loved one stop substance use and change the behavior that is so destructive. However, the substance user often relies on others to rescue them by covering up own inability to cope with daily responsibilities.
Provide information about enabling behavior, addictive disease characteristics for both user and nonuser.	Awareness and knowledge of behaviors such as avoiding and shielding, taking over responsibilities, rationalizing, and subservience provide opportunity for individuals to begin the process of change.
Identify and discuss sabotage behaviors of family members.	Even though family member(s) may verbalize a desire for the individual to become substance-free, the reality of interactive dynamics is that they may unconsciously not want the individual to recover because this would affect their own role in the relationship. Additionally, they may receive sympathy and attention from others—secondary gain.
Encourage participation in therapeutic writing, such as journaling (narrative) or guided or focused writing.	Serves as a release for feelings such as anger, grief, and stress and helps move individuals forward in treatment process.
Provide factual information to client and family about the effects of addictive behaviors on the family and what to expect after discharge.	Many clients and SOs are not aware of the nature of addiction. If client is using legally obtained drugs, he or she may believe this does not constitute abuse.
Encourage family members to be aware of their own feelings and look at the situation with perspective and objectivity. They can ask themselves, "Am I being conned? Am I acting out of fear, shame, guilt, or anger? Do I have a need to control?"	When the enabling family members become aware of their own actions that perpetuate the addict's problems, they need to decide to change themselves. If they change, the client can then face the consequences of his or her own actions and may choose to get well.
Provide support for enabling partner(s). Encourage group work.	Families and SOs need support to produce change as much as the person who is addicted.
Assist the client's partner to become aware that client's abstinence and drug use are not the partner's responsibility.	Partners need to learn that user's habit may or may not change despite partner's involvement in treatment.
Help the recovering partner who is enabling to distinguish between destructive aspects of behavior and genuine motivation to aid the user.	Enabling behavior can be partner's attempts at personal survival.
Note how partner relates to the treatment team.	Determines enabling style. A parallel exists between how partner relates to user and to staff, based on partner's feelings about self and situation.
Explore conflicting feelings the enabling partner may have about treatment, such as feelings similar to those of abuser—blend of anger, guilt, fear, exhaustion, embarrassment, loneliness, distrust, grief, and possibly relief.	Useful in establishing the need for therapy for the partner. This individual's own identity may have been lost; she or he may fear self-disclosure to staff and may have difficulty giving up the dependent relationship.
Involve family in discharge referral plans.	Drug abuse is a family illness. Because the family has been so involved in dealing with the substance use behavior, family members need help adjusting to the new behavior of sobriety and abstinence. Incidence of recovery is almost doubled when the family is treated along with the client.
Be aware of staff's enabling behaviors and feelings about client and enabling partners.	Lack of understanding of enabling can result in nontherapeutic approaches to clients and their families.
<b>Collaborative</b>	
Involve in substance abuse prevention or treatment plan, as indicated.	Can be voluntary, court ordered, or via the Department of Human Services (DHS) involvement. <b>P</b> Prevention programs should address all forms of drug use, alone or in combination, including the underage use of legal drugs (e.g., tobacco or alcohol), the use of illegal drugs (e.g., marijuana [real and counterfeit] such as 9K2, Spice), meth, cocaine, other designer drugs, including Ecstasy, and the

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
P Promote involvement of all members in multidimensional family therapy.	inappropriate use of legally obtained substances (e.g., inhalants), prescription medications, or over-the-counter drugs (Johnston et al, 2002).
Encourage involvement with self-help associations, AA or NA, Al-Anon, Alateen, and professional family therapy.	Program developed for adolescents with SUDs and their families to address the various influences on client's drug abuse patterns, which is designed to improve overall family functioning by fostering family competency and collaboration with other systems such as school and juvenile justice (SAMHSA, 2015).

NURSING DIAGNOSIS: Sexual Dysfunction
<b>May Be Related To</b>
Alteration in body function (e.g., neurological damage, debilitating effects of drug use—particularly alcohol and opiates) Vulnerability; presence of abuse Value conflict (gender identity, sexual preferences) Insufficient knowledge, misinformation
<b>Possibly Evidenced By</b>
Decrease in sexual desire Alteration in sexual activity, satisfaction Undesired change in sexual function
<b>Desired Outcomes/Evaluation Criteria—Client Will</b>
<b>Substance Addiction Consequences NOC</b> Verbally acknowledge effects of drug use on sexual functioning and reproduction.
<b>Sexual Functioning NOC</b> Identify interventions to correct and overcome individual situation.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Sexual Counseling NIC</b> <i>Independent</i>	
Ascertain client's beliefs and expectations. Have client describe problem in own words.	Determines level of knowledge, identifies misperceptions, level of concern regarding sexually transmitted infections (STIs), level of risk reduction, and specific learning needs.
Encourage and accept individual expressions of concern.	Most people find it difficult to talk about this sensitive subject and may not ask directly for information.
Provide educational opportunities such as pamphlets or consultation with appropriate persons regarding effects of drug on sexual functioning.	Much of denial and hesitancy to seek treatment may be reduced as a result of sufficient and appropriate information.
Provide information about individual's condition.	Sexual functioning may have been affected by the drug itself and/or by psychological factors, such as stress or depression. Information can assist client to understand own situation and identify actions to be taken.
Assess drinking and drug history of pregnant client. Provide information about effects of substance abuse on the reproductive system and fetus, including increased risk of premature birth, brain damage, and fetal malformation.	Awareness of the negative effects of alcohol and other drugs on reproduction may motivate client to stop using substance. When client is pregnant, identification of potential problems aids in identifying concerns and planning for future fetal needs.
Discuss prognosis for sexual dysfunction, such as impotence or low sexual desire.	Impotence may be reversed with abstinence from drug(s) for many individuals; however, for some, erectile dysfunction will be permanent.

(continues on page 944)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<b>Collaborative</b> Refer for sexual counseling, if indicated.	Couple may need additional assistance to resolve more severe problems or situations. Client may have difficulty adjusting if drug has improved sexual experience, such as heroin, which decreases dyspareunia in women and premature ejaculation in men. Furthermore, the client may have engaged enjoyably in bizarre, erotic sexual behavior under influence of the stimulant drug; client may have found no substitute for the drug, may have driven a partner away, and may have no motivation to adjust to sexual experience without drugs.
Review results of sonogram if pregnant.	Assesses fetal growth and development to identify possibility of fetal alcohol syndrome or other harmful drug effects and future needs. There are concerns about placental abruption with the use of methamphetamine and cocaine.

**NURSING DIAGNOSIS:** **deficient Knowledge regarding condition, prognosis, treatment, self-care, and discharge needs**

**May Be Related To**

Insufficient information, insufficient knowledge of resources  
Alteration in cognitive functioning

**Possibly Evidenced By**

Insufficient knowledge; insufficient interest in learning  
Inaccurate follow-through of instructions  
Inappropriate behavior

**Desired Outcomes/Evaluation Criteria—Client Will**

**Knowledge: Substance Abuse Control NOC**

Verbalize understanding of own condition or disease process, prognosis, and potential complications.  
Verbalize understanding of therapeutic needs.  
Identify and initiate necessary lifestyle changes to remain drug-free.  
Participate in treatment program including plan for follow-up and long-term care.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Learning Facilitation NIC</b>	
<b>Independent</b>	
Be aware of and deal with anxiety of client and family members.	Anxiety can interfere with ability to hear and assimilate information.
Provide an active role for the client and SO in the learning process using discussions, group participation, and role-playing.	Learning is enhanced when persons are actively involved.
Provide written and verbal information as indicated. Include list of articles, books, Internet resources, and special TV programs related to client and family needs and encourage reading and discussing what they learn.	Helps client and SO make informed choices about future and can be a useful addition to other therapeutic approaches.
Assess client's knowledge of own situation, including disease process (including comorbidities), prognosis, complications, and needed changes in lifestyle.	Assists in planning for long-range changes necessary for maintaining sobriety and drug-free status. Client may have street knowledge of the drug but be ignorant of medical facts.
Pace learning activities to individual needs.	Facilitates learning because information is more readily assimilated when timing is considered.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
<b>Teaching: Disease Process NIC</b> Review condition, prognosis, and future expectations.	Provides knowledge base from which client can make informed choices.
Discuss relationship of drug use to current situation.	Often client has misperception or denial of real reason for admission to the medical or psychiatric care setting.
Educate about effects of specific drug(s) used; for example, PCP is deposited in body fat and may reactivate, causing flashbacks even after long interval of abstinence; alcohol use may result in mental deterioration and liver involvement or damage; cocaine can damage postcapillary vessels and increase platelet aggregation, promoting thromboses and infarction of skin or internal organs, causing localized atrophie blanche or sclerodermatos lesions.	Information will help client understand possible long-term effects of drug use.
Discuss potential for reemergence of withdrawal symptoms in stimulant abuse as early as 3 months or as late as 9 to 12 months after discontinuing use.	Even though intoxication may have passed, client may manifest denial, drug hunger, and periods of "flare-up," wherein there is a delayed recurrence of withdrawal symptoms such as anxiety, depression, irritability, sleep disturbance, or compulsiveness with food, especially sugars.
Inform client of effects of disulfiram (Antabuse) in combination with alcohol intake and importance of avoiding use of alcohol-containing products such as cough syrups, foods, candy, mouthwash, aftershave, and cologne.	Interaction of alcohol and Antabuse results in nausea and hypotension, which may produce fatal shock. Individuals on Antabuse are sensitive to alcohol on a continuum, with some being able to drink while taking the drug and others having a reaction with only slight exposure. Reactions also appear to be dose related.
Review specific aftercare needs; for example, PCP user should drink cranberry juice and continue use of ascorbic acid; alcohol abuser with liver damage should refrain from drugs, anesthetics, or use of household cleaning products that are detoxified in the liver.	Promotes individualized care related to specific situation. Cranberry juice and ascorbic acid enhance clearance of PCP from the system. Substances that have the potential for liver damage are more dangerous in the presence of an already damaged liver.
Discuss variety of helpful organizations and programs that are available for assistance or referral such as AA, Dual Recovery Anonymous (DRA), or NA.	Long-term support is necessary to maintain optimal recovery. Psychosocial needs and other issues may need to be addressed.

**POTENTIAL CONSIDERATIONS** following acute care (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

- **ineffective Health Management/ineffective family Health Management**—decisional conflicts, excessive demands made on individual or family, family conflict, perceived seriousness/benefits
- **ineffective Coping**—situational crises, inadequate level of confidence in ability to cope, inadequate level of perception of control
- **readiness for enhanced family Coping**—significant person moves in direction of health promotion, chooses experiences that optimize wellness

Physical needs depend on substance effect on organ systems—refer to appropriate medical plans of care for additional considerations.

## CANCER—GENERAL CONSIDERATIONS

### I. Pathophysiology

- a. General term describing a disturbance of cellular growth and referring to a group of 150 different known diseases or types
- b. Genetic and genomic factors underlie the etiology of all cancer. The alteration of genes manifests in abnormal

cellular proliferation. Genes and genomic alterations often occur due to multifactorial genetic, infectious, radiation, environmental, hormonal, or lifestyle factors (Santos et al, 2013).

- c. The metastatic behavior or "natural history" of cancer varies according to the primary site of diagnosis—

(continues on page 946)

metastatic pattern for primary breast cancer may be from the breast to the bone, lung, liver, and/or brain.

## II. Classification

- a. Four main classifications of cancer according to tissue type:
  - i. Lymphomas: cancers originating in infection-fighting organs
  - ii. Leukemias: cancers originating in blood-forming organs
  - iii. Sarcomas: cancers originating in bones, muscle, or connective tissue
  - iv. Carcinomas: cancers originating in epithelial cells
- b. Within these broad categories, a cancer is classified by histology, stage, and grade (tumor profiling).

## III. Etiology

- a. Cellular disease that can arise from any body tissue with manifestations that result from failure to control the proliferation and maturation of cells
- b. Multiple risk factors or cancer-causing agents:
  - i. Chemicals
  - ii. Radiation
  - iii. Viruses
  - iv. Human behaviors and lifestyles that affect cancer risk
  - v. Tobacco use
  - vi. Poor nutrition
  - vii. Inactivity, obesity
  - viii. Sun exposure

- ix. Workplace or occupational exposure
  - x. Pollution—air, water, soil
- c. Biological factors that may increase or reduce risk:
    - i. Inflammation
    - ii. DNA repair mechanisms
    - iii. Immunologic responses
    - iv. Heredity
      1. 75% of cancers are sporadic or manifest in one body organ at an expected age.
      2. 10% to 15% are familial, or two or more siblings are diagnosed with the same cancer at a specific age.
      3. 5% to 10% of cancers are hereditary or the result of a single gene expression (Santos et al, 2013).

## IV. Statistics

- a. Morbidity: In 2018, the American Cancer Society (ACS) projected 1,735,350 new cancer cases in the United States. In 2010, cancer was the first-listed diagnosis in 1.2 million hospital discharges (CDC, 2010b).
- b. Mortality: The American Cancer Society (ACS) estimates almost 610,000 deaths from all types of cancer in 2018.
- c. Cost: The National Cancer Institute (NCI) reports that national expenditures for cancer care in 2016 were an estimated \$63.8 billion just for the top 5 cancers of 18 listed types (breast, colorectal, prostate, lymphoma, and lung) (NCI, 2017).

## G L O S S A R Y

**Adenocarcinoma:** Cancer arising in gland-forming tissue. An example is breast cancer.

**Adjuvant therapy:** Treatment given in addition to the primary treatment.

**Alopecia:** Hair loss.

**Biotherapy:** Treatment to boost or restore the ability of the immune system to fight cancer. Also used to decrease the side effects caused by some cancer treatments. Agents used in biotherapy include monoclonal antibodies, growth factors, and vaccines.

**Cachexia:** Loss of body weight and muscle mass as a result of anorexia, nausea and vomiting, or hypermetabolism.

**Cancer-related fatigue (CRF):** Persistent and subjective sense of tiredness that can occur with cancer or cancer treatment, which interferes with usual functioning and can drastically affect the client's quality of life.

**Carcinogen:** Any substance that causes cancer.

**Carcinoma:** Cancer that begins in the lining or covering of an organ.

**Desquamation:** Shedding of the skin as a reaction to radiotherapy. In its mildest form, it is "dry" when the skin flakes in a powdery form. In a more severe form ("wet"), the deeper layers of the skin are exposed.

**Genome:** The expanded study of genetics that no longer focuses on specific genes but on a person's entire genetic content and interacting factors that regulate or modify gene expression (Santos et al, 2013).

**Holistic Needs Assessment (HNA):** Specific terminology to describe assessing all aspects of the life of a client diagnosed with cancer (Taylor et al, 2012). In the United States, this term is synonymous with palliative needs assessment.

**Metastasis:** Spread of cancer to another organ, usually through the bloodstream.

**Mucositis:** A complication of some cancer therapies in which the lining of the digestive system becomes inflamed; often seen as sores in the mouth.

**Nadir:** Period of time following chemotherapy treatment when blood counts generally are at their lowest levels and client is at greatest risk of developing infection and other blood-related side effects.

**Palliative care:** "An approach that improves the quality of life of patients and their families facing the problems associated with life-limiting illness, through the prevention and relief of suffering by means of early identification and impeccable assessment and treatment of pain and other problems, physical, psychosocial and spiritual" (World Health Organization [WHO], 2002).

**Peripheral progenitor cell (stem cell) transplant:** Method of replacing blood-forming cells destroyed by cancer treatment. Immature blood cells (stem cells) in the circulating blood that are similar to those in the bone marrow are given to the client after treatment.

**Radiation dermatitis:** Skin condition that is a common side effect of radiation therapy. The affected skin becomes painful, red, itchy, and blistered.

**Staging:** Classification of the primary tumor (T), lymph node involvement (N), combined with tests to see if the cancer has metastasized (M).

**Stomatitis:** Inflammation of the mucous membranes of the mouth.

**Superior vena cava syndrome (SVCS):** Condition in which a tumor presses against the superior vena cava—the large vein that carries blood from the head, neck, arms, and

**G L O S S A R Y** (continued)

- chest to the heart. This pressure blocks blood flow to the heart and may cause coughing, difficulty in breathing, and swelling of the face, neck, and upper arms.
- Tumor:** An abnormal mass of tissue, either benign (noncancerous) or malignant (cancerous).
- Tumor marker:** Substance detectable in the blood or urine that suggests the presence of cancer.
- Vein flare:** Painless local allergic reaction identified by redness along the vein used to infuse chemotherapeutic agent; urticaria or hives may also be present. Usually subsides within 30 to 60 minutes without treatment.

**Weight-related distress (WDR) and/or eating-related distress (ERD):** Syndrome, common in advanced cancer, and characterized by resistance to eating, poor and capricious appetite, a disconnection of oral intake and ability to gain weight, or continuous efforts to eat. The client's SOs may have feelings of deep concern, frustration, and insufficiency in their efforts to prepare appealing food and be more concerned about client's weight loss than is the client (also sometimes known as "anorexia-cachexia syndrome") (Hopkinson et al, 2013).

**CARE SETTING**

Cancer centers may focus on staging and major treatment modalities for complex cancers. Treatment for managing adverse effects, such as malnutrition and infection, may take place in short-stay, ambulatory, or community setting. More cancer clients are receiving care at home because of personal choice and healthcare costs. **P** *Cancer treatment needs to be age and life stage appropriate. Over 70% of children diagnosed with cancer mature into adulthood and present with special nursing needs (McInally & Cruickshank, 2013).*

**RELATED CONCERNs**

- Adult leukemias, page 569
- Adult lymphomas, page 582
- Hysterectomy, page 666
- Lung cancer: postoperative care, page 159
- Mastectomy, page 675
- Palliative/end-of-life care—hospice, page 970
- Pediatric considerations, page 993
- Prostatectomy, page 694
- Psychosocial aspects of care, page 835
- Sepsis/septic shock, page 772
- Total nutritional support: parenteral/enteral feeding, page 525
- Urinary diversions/urostomy (postoperative care), page 645

**CLIENT ASSESSMENT DATABASE**

Data depend on organs or tissues involved and stage of disease. A holistic needs assessment (HNA) should be completed for every client/family diagnosed with cancer to prioritize care (Taylor et al, 2012). Refer to appropriate plans of care for additional assessment information.

**DIAGNOSTIC DIVISION  
MAY REPORT****ACTIVITY/REST**

- Weakness and fatigue (most prevalent problems reported by clients with advanced cancer) (Girgis et al, 2006)
- Changes in rest pattern and usual hours of sleep per night
- Presence of factors affecting sleep, such as pain, anxiety, night sweats, more frequent elimination needs
- Limitations of participation in hobbies, exercise, usual activities

**CIRCULATION**

- Palpitations
- Chest pain on exertion

**EGO INTEGRITY**

- Stress factors—financial, job, role changes
- Ways of handling stress—smoking, drinking, delay in seeking treatment, religious or spiritual crisis

**MAY EXHIBIT**

- Inability to maintain usual routines or desired level of activity or work
- Lack of energy
- Disinterest in surroundings
- Compromised concentration

- Changes in blood pressure (BP)
- Fluctuations in heart rate

- Denial, withdrawal, anger
- Depression

(continues on page 948)

**CLIENT ASSESSMENT DATABASE (contd.)****MAY REPORT (continued)**

- Concern about changes in body image (e.g., alopecia, disfiguring lesions, surgery, profound weight loss, edema, weight gain, or rash)
- Denial of diagnosis
- Feelings of powerlessness, hopelessness, helplessness, worthlessness, guilt, loss of control
- Eating-related distress (ERD) or weight-related distress (WRD): Client and caregivers may express feelings of frustration, hopelessness, pressure, failure to meet expectations (Hopkinson et al, 2013).

**ELIMINATION**

- Changes in bowel pattern—blood in stools, pain with defecation, constipation, or diarrhea
- Changes in urinary elimination—pain or burning on urination, hematuria, frequent urination or nocturia

**FOOD/FLUID**

- Poor dietary habits,
- Anorexia, resistance to eating, poor, or capricious appetite (ERD, WRD)
- Altered sense of taste
- Nausea and vomiting
- Difficulty swallowing, mouth sores
- Food intolerances

**NEUROSENSORY**

- Dizziness, syncope
- Lack of coordination, unstable balance
- Numbness or tingling of extremities
- Sensation of coldness
- Difficulty performing fine motor skills such as buttoning shirt

**PAIN/DISCOMFORT**

- Varying degrees of pain from mild discomfort to severe pain. Younger age (<65) may be associated with a higher prevalence of pain and may also be associated with severity of pain (Girgis et al, 2006).
- Pain localized in a specific area
- Quality or description
  - Stabbing, throbbing, dull, aching (somatic pain often present with surgery or metastases in bone)
  - Pressure-like, cramping, gnawing, squeezing—visceral pain that may be referred from one site to another
  - Sharp, burning, shooting pain; may be accompanied by numbness and tingling in extremities—neuropathic pain caused from damage to nervous system

**RESPIRATION**

- Dyspnea with exertion
- History of chronic respiratory disease
- Smoking—tobacco, marijuana
- Living with someone who smokes
- Asbestos or dust exposure—coal, sandstone, silica, and the like

**SAFETY**

- Occupational, professional, or environmental exposure to toxic chemicals, carcinogens
- Excessive or prolonged sun exposure

**MAY EXHIBIT (continued)**

- Changes in bowel sounds
- Abdominal distention
- Diarrhea
- Dysuria, frequency, incontinence

- Changes in weight, severe weight loss, cachexia
- Wasting of muscle mass
- Changes in skin moisture or turgor
- Edema
- Ulcerations of oral mucosa

- Guarding behaviors, positioning to avoid pain
- Facial mask
- Sleep disturbance
- Restlessness, moaning, crying, irritability, lethargy
- Self-focusing; narrowed focus
- Reduced interaction with others
- Depression

- Skin rashes, ulcerations
- Dry, leather-like skin

**MAY REPORT (continued)****MAY EXHIBIT (continued)****SEXUALITY**

- Sexual concerns such as impact on relationship, change in level of satisfaction, impotence, menopausal symptoms
- Nulligravida greater than 30 years of age, multigravida
- Multiple sex partners, early sexual activity, genital herpes
- Exposure to human papillomavirus (HPV)

**SOCIAL INTERACTION**

- Inadequate or weak support system
- Marital history regarding in-home satisfaction, support, or help
- Concerns about role function and responsibility

**TEACHING/LEARNING**

- Family history of cancer, for example, multiple family members—mother, grandmother, aunt, or sister—with breast cancer (Santos et al, 2013)
- Primary site, date discovered or diagnosed
- Metastatic disease—additional sites involved (if none, natural history of primary will provide important information for looking for metastasis)
- Treatment history—previous treatment for cancer—place and treatments given

**DISCHARGE PLAN CONSIDERATIONS**

- May require assistance with finances, medications, treatments, wound care and supplies, transportation, food shopping and preparation, self-care, homemaker or maintenance tasks, provision for child care, changes in living facilities, or hospice

► Refer to section at end of plan for postdischarge considerations.

**DIAGNOSTIC STUDIES**

Test selection depends on history, clinical manifestations, and index of suspicion for a particular cancer.

TEST WHY IT IS DONE	WHAT IT TELLS ME
<b>BLOOD TESTS</b> <ul style="list-style-type: none"> <li>• <b>Tumor markers:</b> Substances produced and secreted by tumor cells and found in serum; for example, carcinoembryonic antigen (CEA), prostate-specific antigen (PSA), alpha-fetoprotein (AFP), human chorionic gonadotropin (hCG), CA15-3, CA19-9, and CA125.</li> <li>• <b>Hormone receptors:</b> Estrogen and progesterone receptor assay done on breast tissue.</li> <li>• <b>Her-2/neu amplification:</b> Cellular proto-oncogene that stimulates cell growth.</li> <li>• <b>Gene mutations:</b> BRCA-1 and BRCA-2 function as tumor suppressor genes.</li> </ul>	<p>Helpful in diagnosing cancer but more useful as prognostic indicator and/or therapeutic monitor. For example, CA125 levels are monitored in ovarian cancer, with levels often high prior to surgery but should be lower after surgery or with a response to chemotherapy. If the cancer begins to grow, the CA125 level will usually begin to increase before any other signs or symptoms are evident.</p> <p>Provides information about whether or not hormonal manipulation can be therapeutic in breast cancer treatment.</p> <p>Amplification (a large number of these receptors found on the cell surface) results in more aggressive breast cancers and, usually, a worse prognosis with earlier appearance of metastatic disease.</p> <p>If these genes are mutated, there may be an increased lifetime risk of acquiring breast, ovarian, prostatic, and possibly other cancers.</p> <p>(continues on page 950)</p>

## DIAGNOSTIC STUDIES (contd.)

WHY IT IS DONE (continued)	WHAT IT TELLS ME (continued)
<ul style="list-style-type: none"><li><b>Immunohistochemistry (IHC) tumor profiling:</b> Staining of cells/biopsied tissues with specific antibodies.</li><li><b>Complete blood count (CBC):</b> Battery of screening tests, which typically includes hemoglobin (Hgb); hematocrit (Hct); red blood cell (RBC) count, morphology, indices, and distribution width index; platelet count and size; and white blood cell (WBC) count and differential.</li></ul>	<p>IHC is helpful in determining the stage and grade of a tumor, as well as cell type and origin of metastasis to identify primary site (American Cancer Society, 2013).</p> <p>May reveal anemia, changes in RBCs and WBCs, and reduced or increased platelets.</p>
<b>OTHER DIAGNOSTIC STUDIES</b> <ul style="list-style-type: none"><li><b>Scans—magnetic resonance imaging (MRI), computed tomography (CT), positron emission tomography (PET), or ultrasound:</b> May be done for diagnostic purposes, identification of metastasis, and evaluation of response to treatment.</li><li><b>Biopsy—fine-needle aspiration (FNA), needle core, incisional or excisional:</b> May be taken from various sites, such as bone marrow (e.g., leukemia), skin, or organ.</li></ul>	<p>Knowledge of the etiology and natural history or pattern of metastasis of a cancer type is important in planning the client's care and in evaluating the client's progress, prognosis, and physical complaints.</p> <p>Differentiates diagnosis and delineates treatment options.</p>

## NURSING PRIORITIES

1. Support adaptation and independence.
2. Promote comfort.
3. Maintain optimal physiological functioning.
4. Prevent complications.
5. Provide information about disease process, condition, prognosis, and treatment needs.

## DISCHARGE GOALS

1. Dealing with current situation realistically.
2. Pain alleviated or controlled.
3. Homeostasis achieved.
4. Complications prevented or minimized.
5. Disease process, condition, prognosis, and therapeutic choices and regimen understood.
6. Plan in place to meet needs after discharge.

## NURSING DIAGNOSIS: **Fear/Anxiety [specify level]**

### May Be Related To

Situational crisis  
Major change (e.g., health status, economic status, role function)  
Threat of death  
Separation from support systems  
Interpersonal transmission or contagion

### Possibly Evidenced By

Increase in tension, shakiness; apprehensiveness, distressed, fear  
Worried about change in life event; restlessness, insomnia  
Feeling inadequate; decrease in self-assurance  
Changes in BP, pulse, respirations

### Desired Outcomes/Evaluation Criteria—Client Will

#### **Fear [or] Anxiety Self-Control NOC**

Display appropriate range of feelings and lessened fear.  
Appear relaxed and report anxiety is reduced to a manageable level.  
Demonstrate use of effective coping mechanisms and active participation in treatment regimen.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Anxiety Reduction NIC</b>	
<b>Independent</b>	
Review client's and significant other's (SO's) previous experience with cancer. Determine what the doctor has told client and what conclusion client has reached.	Clarifies client's perceptions; assists in identification of fear(s) and misconceptions based on diagnosis and experience with cancer.
Encourage client to share thoughts and feelings.	Provides opportunity to examine realistic fears and misconceptions about diagnosis.
Provide open environment in which client feels safe to discuss feelings or to refrain from talking.	Helps client feel accepted in present condition without feeling judged and promotes sense of dignity and control.
Maintain frequent contact with client. Talk with and touch client, as appropriate.	Provides assurance that the client is not alone or rejected; conveys respect for and acceptance of the person, fostering trust.
Be aware of effects of isolation on client when required by immunosuppression or radiation implant. Limit use of isolation clothing, as possible.	Sensory deprivation may result when sufficient stimulation is not available and may intensify feelings of anxiety, fear, and alienation.
Assist client and SO in recognizing and clarifying fears to begin developing coping strategies for dealing with these fears.	Coping skills are often stressed after diagnosis and during different phases of treatment. Support and counseling are often necessary to enable individual to recognize and deal with fear and to realize that control and coping strategies are available.
Provide accurate, consistent information regarding diagnosis and prognosis. Avoid arguing about client's perceptions of situation.	Can reduce anxiety and enable client to make decisions and choices based on realities. Challenging client's views may increase anxiety and damage working relationship with staff.
Permit expressions of anger, fear, and despair without confrontation. Give information that feelings are normal and are to be appropriately expressed.	Acceptance of feelings helps client feel safe and allows client to begin to deal with situation.
Explain the recommended treatment, its purpose, and potential side effects. Help client prepare for treatments.	The goal of cancer treatment is to destroy malignant cells while minimizing damage to normal ones. Treatment may include curative, preventive, or palliative surgery as well as chemotherapy, internal or external radiation, or newer, organ-specific treatments such as whole-body hyperthermia or biotherapy. Bone marrow or peripheral progenitor cell transplant may be recommended for some types of cancer.
Explain procedures, providing opportunity for questions. Respond truthfully, providing honest answers reflecting client's age/developmental level.	Accurate information allows client to deal more effectively with reality of situation, thereby reducing anxiety and fear of the unknown. Note: The focus of client's fears/concerns can be affected by the individual's age, gender, values, and beliefs.
Stay with client during anxiety-producing procedures and consultations and provide physical comfort as appropriate.	Physical contact (e.g., holding hand of adult/adolescent, hugging or rocking a child) helps to soothe fears and provide reassurance.
Provide primary and consistent caregivers whenever possible.	May help reduce anxiety by fostering therapeutic relationship and facilitating continuity of care.
Provide calm, quiet environment.	Facilitates rest, conserves energy, and may enhance coping abilities.
Identify stage and degree of grief client and SO are currently experiencing. (Refer to ND: Grieving, following.)	Choice of interventions is dictated by stage of grief and negative coping behaviors, such as anger, withdrawal, and denial.
Note ineffective coping such as poor social interactions, helplessness, giving up everyday functions and usual sources of gratification.	Identifies individual problems and provides support for client and SO in using effective coping skills. Note: Studies have found that clients with unmet needs in physical symptom control, occupational functioning, nutrition, sleep, and personal care demonstrate higher symptom distress and psychological distress (Girgis et al, 2006).

(continues on page 952)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Be alert to signs of denial or depression, such as withdrawal and anger or making inappropriate remarks. Determine presence of suicidal ideation and assess potential on a scale of 1 to 10.	Client may use defense mechanism of denial and express hope that diagnosis is inaccurate. Feelings of guilt, spiritual distress, physical symptoms, or lack of cure may cause the client to become withdrawn and believe that suicide is a viable alternative.
Encourage and foster client interaction with support systems, including counselors, spiritual leader, and local cancer resources.	Reduces feelings of isolation. If family support systems are not available, outside sources may be needed immediately.
Provide reliable and consistent information and support for SO.	Allows for better interpersonal interaction and reduction of anxiety and fear.
Include SO as indicated and client desires when major decisions are to be made.	Provides a support system for the client and allows the SO to be involved appropriately.
<b>Collaborative</b> Administer antianxiety medications, such as lorazepam (Ativan) or alprazolam (Xanax), as indicated.	May be useful for brief periods of time to help client handle feelings of anxiety related to diagnosis or situation during periods of high stress, to assist client with diagnostic procedures, such as lying still during scan, and/or to minimize nausea.
Refer to additional resources for counseling and support as needed.	May be useful from time to time to assist client and SO in dealing with anxiety.

## NURSING DIAGNOSIS: **Grieving**

### May Be Related To

Anticipated loss of significant object—body part and processes of body, job, status, home  
Potential of death

### Possibly Evidenced By

Pain; suffering  
Alteration in activity level, sleep pattern  
Despair; anger; blaming

### Desired Outcomes/Evaluation Criteria—Client Will

#### **Grief Resolution NOC**

Identify and express feelings appropriately.  
Continue normal life activities, looking toward and planning for the future, one day at a time.  
Verbalize reality and acceptance of situation.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Grief Work Facilitation NIC</b>	
<b>Independent</b>	
Expect initial shock and disbelief following diagnosis of cancer and/or traumatizing procedures such as disfiguring surgery, colostomy, and amputation.	Few clients are fully prepared for the reality of the changes that can occur.
Assess client and SO for stage of grief currently being experienced. Explain process, as appropriate.	Knowledge about the grieving process reinforces the normalcy of feelings and reactions being experienced, helping client deal more effectively with them.
Provide open, nonjudgmental environment. Use therapeutic communication skills of active-listening, acknowledgment, and so on.	Promotes and encourages realistic dialogue about feelings and concerns.
Encourage verbalization of thoughts and concerns, accepting expressions of sadness, anger, and rejection. Acknowledge normalcy of these feelings.	Client may feel supported in expression of feelings by the understanding that deep and often conflicting emotions are normal and experienced by others in this difficult situation.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Be aware of mood swings, evidence of conflict, expressions of anger or hostility, and other acting-out behavior. Set limits on inappropriate behavior and redirect negative thinking.	May be client's way of expressing or dealing with feelings of despair and spiritual distress, reflecting ineffective coping and need for additional interventions. Preventing destructive actions enables client to maintain control and sense of self-esteem.
Note signs of debilitating depression. Ask client direct questions about state of mind. Listen for statements of despair, guilt, and hopelessness, such as "There's nothing to live for."	Studies show that clients with physical illnesses are at higher risk for suicide (Aiello-Laws, 2010; Taur et al, 2013). They are especially vulnerable when recently diagnosed and/or discharged from hospital.
Reinforce teaching regarding disease process and treatments. Be honest; avoid giving false hope while providing emotional support.	Client and SO benefit from factual information. Honest answers promote trust and provide reassurance that correct information will be given.
Review past life experiences, role changes, and coping skills.	Opportunity to identify skills that may help individuals cope with grief of current situation more effectively.

**Hope Instillation NIC**

Identify positive aspects of the situation.	Possibility of remission and slow progression of disease and/or new therapies can offer hope for the future.
Discuss ways client and SO can plan together for the future. Encourage setting of realistic goals.	Having a part in problem-solving and planning can provide a sense of control over anticipated events.
Assist client and SO to identify strengths in self, situation, and support systems.	Recognizing these resources provides opportunity to work through feelings of grief.
Encourage participation in care and treatment decisions.	Allows client to retain some control over life.
<b>Collaborative</b>	
Refer to visiting nurse, home health agency as needed, or hospice program, if appropriate.	Provides support in meeting physical and emotional needs of client and SO and can supplement the care family and friends are able to give.
Refer to appropriate counselor as needed, such as psychiatric clinical nurse specialist, social worker, hospice counselor, psychologist, and clergy.	Can help alleviate distress or palliate feelings of grief to facilitate coping and foster growth.

Refer to CP: Palliative/end-of-life care—hospice; ND: Grieving/Death Anxiety for additional interventions.

**NURSING DIAGNOSIS: risk for situational low Self-Esteem****Possibly Evidenced By**

Physical illness  
Alteration in body image; functional impairment  
Decrease in control over environment

**Desired Outcomes/Evaluation Criteria—Client Will****Self-Esteem NOC**

Verbalize understanding of body changes, acceptance of self in situation.  
Begin to develop coping mechanisms to deal effectively with problems.  
Demonstrate adaptation to changes and events that have occurred as evidenced by setting of realistic goals and active participation in work, play, and personal relationships, as appropriate.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Chemotherapy [or] Radiation Therapy Management NIC</b> <i>Independent</i>	Aids in defining concerns to begin problem-solving process.

(continues on page 954)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Verify client's concept of self in relation to cultural/religious beliefs.	Cultural and religious influences during the individual's life affect beliefs about self, measure of worth, and ability to deal with current situation.
Review anticipated side effects associated with a particular treatment, such as alopecia or disfiguring surgery, including possible effects on sexual activity and sense of attractiveness or desirability. Tell client that not all side effects occur and that others may be minimized.	Anticipatory guidance can help client and SO begin the process of adaptation to new state and to prepare for some side effects, such as buying a wig before radiation and scheduling time off from work, as indicated. (Refer to ND: risk for Sexual Dysfunction.)
Engage in prechemotherapy group sessions led by nurses.	Group information sessions are improving cancer treatment experiences and outcomes, ensuring consistent information is provided and establishing an early support system for clients and families (Sullivan et al, 2013).
Encourage discussion of and problem-solve concerns about effects of cancer or cancer treatments on role as home-maker, wage earner, or parent.	May help reduce problems that interfere with acceptance of treatment or aggravate progression of disease.
Acknowledge difficulties client may be experiencing. Give information that counseling is often important in the adaptation process.	Validates reality of client's feelings and gives permission to take whatever measures are necessary to cope with what is happening.
Evaluate support structures available to and used by client and SO.	Helps with planning for care while hospitalized and after discharge.
Provide emotional support for client and SO during diagnostic tests and treatment phase.	Although some clients adjust to cancer effects or side effects of therapy, many need additional support during this period.
Use touch during interactions, if acceptable to client, and maintain eye contact.	Affirmation of individuality and acceptance is important in reducing client's feelings of insecurity and self-doubt.
<b>Collaborative</b>	
Refer client and SO to supportive group programs, such as I Can Cope, Reach to Recovery, Man to Man Prostate Cancer Group, or Leukemia/Lymphoma Society.	Group support is usually very beneficial for both client and SO, providing contact with other clients with cancer at various levels of treatment and/or recovery, validating feelings, and assisting with problem-solving.
Refer for professional counseling as indicated.	May be necessary to regain and maintain a positive psychosocial structure, if client and SO support systems are deteriorating.

## NURSING DIAGNOSIS: acute/chronic Pain

### May Be Related To

Biological agent (e.g., neoplasm)

Physical agents (e.g., compression or destruction of nerve tissue, inflammation, metastasis to bones)

Chemical agent (e.g., chemotherapy, radiation therapy)

### Possibly Evidenced By

Self-report of pain characteristics/intensity using standardized pain instrument/scale

Expressive behavior—restlessness, irritability; positioning to ease pain

Self-focused; narrowed focus

Alteration in ability to continue previous activities (ADLs); appetite change; alteration in sleep pattern

Changes in vital signs (acute pain)

### Desired Outcomes/Evaluation Criteria—Client Will

#### Pain Level NOC

Report maximal pain relief or control with minimal interference with activities of daily living (ADLs).

#### Pain Control NOC

Follow prescribed pharmacological regimen.

Demonstrate use of relaxation skills and diversional activities as indicated for individual situation.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Pain Management: Acute/Chronic</b> <b>NIC</b>	
<b>Independent</b>	
Determine pain history, for example, location of pain, frequency, duration, and relief measures used.	Information provides baseline data to evaluate need for, and effectiveness of, interventions. Pain of more than 6 months' duration constitutes chronic pain, which may affect therapeutic choices. Recurrent episodes of acute pain can occur within chronic pain, requiring increased level of intervention.
Assess pain intensity using a tool appropriate to client's age/developmental level and condition. Believe client's report.	Using appropriate assessment tool (e.g., rating scale of 0 to 10 or verbal rating scale—"no pain" to "excruciating pain," <b>P</b> <b>facial expression or Wong-Baker faces pain scale [pediatric, nonverbal], adolescent pediatric pain tool [APPT]</b> ; pain assessment scale for seniors with limited ability to communicate [PACSLAC], behavioral pain scale [BPS]) is necessary to provide true picture of client's pain. Note: The pain experience is an individualized one composed of both physical and emotional responses.
Determine timing and precipitants of "breakthrough" pain when using around-the-clock agents, whether oral, intravenous (IV), topical, transmucosal, epidural, or patch medications.	Pain may occur near the end of the dose interval, indicating need for higher dose or shorter dose interval. Pain may be precipitated by identifiable triggers or occur spontaneously, requiring use of short half-life agents for rescue or supplemental doses.
Evaluate painful effects of particular therapies, such as surgery, radiation, chemotherapy, or biotherapy. Provide information to client and SO about what to expect.	A wide range of discomforts are common, such as incisional pain, burning skin, low back pain, mouth sores, or headaches, depending on the procedure or agent being used. Pain is also associated with invasive procedures to diagnose or treat cancer.
<b>P</b> Encourage presence of parent or caregiver during painful procedures as appropriate.	Provides reassurance and comfort to child.
Provide nonpharmacological comfort measures, such as massage, repositioning, and back rub, as well as diversional activities, such as music, reading, TV, videos, computer games, age-appropriate play therapy.	Promotes relaxation and helps refocus attention.
Encourage use of stress management skills and complementary therapies, such as relaxation techniques, visualization, guided imagery, biofeedback, laughter, music, aromatherapy, and Therapeutic Touch.	Enables client to participate actively in nondrug treatment of pain and enhances sense of control. Pain produces stress and, in conjunction with muscle tension and internal stressors, increases client's focus on self, which in turn increases the level of pain.
Provide cutaneous stimulation, such as heat and cold packs, or massage.	May decrease inflammation, muscle spasms, reducing associated pain.
Be aware of barriers to cancer pain management related to client (e.g., under reporting of pain, age and cultural expectations, misconceptions about medication use) as well as to the healthcare system.	Clients may be reluctant to report pain for reasons such as fear that disease is worse; worry about unmanageable side effects of pain medications; belief that pain has meaning, such as "God wills it," and they should overcome it; or that pain is merited or deserved for some reason (Clinical Oncology, 2017). Healthcare system problems include factors such as inadequate assessment of pain, concern about controlled substances or client addiction, inadequate reimbursement, and cost of treatment modalities.
Evaluate pain relief at regular intervals. Adjust medication regimen as necessary.	Goal is maximum pain control with minimum interference with ADLs.
Inform client and SO of the expected therapeutic effects and discuss management of side effects.	This information helps establish realistic expectations and confidence in own ability to handle what happens.
<b>Collaborative</b>	
Discuss use of alternative or complementary therapies, such as acupuncture, if client desires.	May provide reduction or relief of pain without drug-related side effects.

(continues on page 956)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Develop individualized pain management plan with the client and physician. Provide written copy of plan to client, family/SO, caregivers, and care providers.	An organized plan beginning with the simplest dosage schedules and least invasive modalities improves chance for pain control. Particularly with chronic pain, client and SO must be active participants in pain management, and all care providers need to be consistent.
Administer analgesics, as indicated, for example:	A wide range of analgesics and associated agents may be employed around the clock to manage the complex nature of cancer pain (e.g., inflammatory, neuropathic, ischemic and compression) (Clinical Oncology, 2017). Note: Addiction to or dependency on drug is not a valid concern/excuse for poor pain management.
Opioids such as codeine, morphine (MSContin, Kadian), oxycodone (oxycontin), hydrocodone (Vicodin), hydromorphone (Dilaudid), methadone (Dolophine), fentanyl (Duragesic, Actiq, Fentora), or oxymorphone (Numorphan, Opana)	Effective for localized and generalized moderate to severe pain, with long-acting or controlled-release forms available. Routes of administration include oral, transmucosal, transdermal, nasal, rectal, and subcutaneous, IV, epidural, and intrathecal infusions, which may be delivered via patient-controlled analgesia (PCA). Fentanyl citrate (Oralet) is available as a transmucosal agent that is absorbed through the mucosa of the inner cheek. Note: Intramuscular (IM) route is not recommended for pain medications because absorption is not reliable, in addition to being painful and inconvenient.
Acetaminophen (Tylenol) and NSAIDs, including aspirin, ibuprofen (Motrin, Advil), piroxicam (Feldene), or indomethacin (Indocin)	Adjuvant drugs are useful for mild to moderate pain and can be combined with opioid and other modalities.
Neuraxial techniques (intrathecal or epidural) or nerve blocks (neurolytic techniques)	These techniques are used to target the pathophysiologic origin of pain that is not relieved by conventional pain relief methods (McHugh et al, 2012).
Corticosteroids, such as dexamethasone (Decadron) or prednisone	May be effective in controlling pain associated with inflammatory process, including metastatic bone pain, acute spinal cord compression, and neuropathic pain.
Anticonvulsants, such as phenytoin (Dilantin), valproic acid (Depakote), clonazepam (Klonopin), gabapentin (Neurontin), or pregabalin (Lyrica)	Useful for peripheral pain syndromes associated with neuropathic pain, especially shooting pain, postherpetic neuralgia.
Antidepressants, such as amitriptyline (Elavil), imipramine (Tofranil), doxepin (Sinequan), trazodone (Desyrel), or duloxetine (Cymbalta)	Effective for neuropathic pain (e.g., tingling, burning pain) and pain resulting from surgery, chemotherapy, or nerve infiltration.
Antihistamines, such as hydroxyzine (Atarax, Vistaril)	Mild anxiolytic agent with sedative and analgesic properties. May produce additive analgesia with therapeutic doses of opioids and may be beneficial in limiting opioid-induced nausea or vomiting.
Radioisotopes, such as strontium-89 (Metastron) or Samarium SM 153 Ixidronam (Quadramet)	Effective in treating pain resulting from osteoblastic metastatic bone lesions. Drug onset is about 1 week with duration of 2 to 4 months. May help reduce dosage of opioid analgesics. Note: Bone marrow, WBC, and platelet counts may be suppressed for up to 8 weeks after administration of the drug.
Bisphosphonates, such as pamidronate (Aredia) or zoledronic acid (Zometa)	Specific inhibitors of osteoclastic activity that treat hypercalcemia and reduce bone pain and fractures, especially in multiple myeloma, breast, and prostate cancers.
Provide and instruct in use of PCA, as appropriate.	Provides for timely drug administration, preventing fluctuations in intensity of pain, often at lower total dosage than would be given by conventional methods.
Instruct in use of electrical stimulation (e.g., transcutaneous electrical nerve stimulation [TENS]) unit.	TENS blocks nerve transmission of pain stimulus, providing reduction and relief of pain without drug-related side effects. Can be used in combination with other modalities.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Provide information for medical cannabis when/where appropriate.	Early studies suggest cannabis may be useful in combatting anorexia, chemotherapy-induced nausea and vomiting, pain, insomnia, and depression (Abrams & Guzman, 2015). Cannabinoids could be synergistic with opioids in the relief of pain, resulting in dose reduction of schedule II to IV medications (Stith et al, 2018).
Prepare for and assist with procedures such as nerve blocks, cordotomy, commissural myelotomy, or radiation therapy.	May be used in severe, intractable pain unresponsive to other measures. Note: Radiation is especially useful for bone metastasis and may provide fast onset of pain relief even with only one treatment.
Refer to structured support group, psychiatric clinical nurse specialist, psychologist, or spiritual advisor for counseling, as indicated.	May be necessary to reduce anxiety and enhance client's coping skills, decreasing level of pain. Note: Hypnosis can heighten awareness and help to focus concentration to decrease perception of pain for some individuals.

<b>NURSING DIAGNOSIS:</b> <b>imbalanced Nutrition: less than body requirements</b>	
<b>May Be Related To</b>	
Biological factors (e.g., hypermetabolic state, fatigue)	
Inability to ingest food (e.g., anorexia, gastric irritation, taste distortions, nausea)	
Psychological disorder (e.g., depression)	
<b>Possibly Evidenced By</b>	
Food intake less than recommended daily allowance (RDA)	
Alteration in taste sensation; insufficient interest in food; food aversion	
Body weight 20% or more below ideal weight range	
Abdominal cramping; sore buccal cavity	
[Abnormal lab values (e.g., decreased albumin, total protein; electrolyte imbalances)]	
<b>Desired Outcomes/Evaluation Criteria—Client Will</b>	
<b>Nutritional Status NOC</b>	
Demonstrate stable weight or progressive weight gain toward goal.	
Display normalization of laboratory values and be free of signs of malnutrition.	
<b>Adherence Behavior: Healthy Diet NOC</b>	
Verbalize understanding of individual interferences to adequate intake.	
Participate in specific interventions to stimulate appetite and increase dietary intake.	

ACTIONS/INTERVENTIONS	RATIONALE
<b>Nutrition Therapy NIC</b>	
<b>Independent</b>	
Monitor daily food intake and have client keep food diary, as indicated. Note pediatric concerns/needs related to growth phase, metabolic, or malabsorption problems.	Identifies nutritional strengths and deficiencies.
Measure height, weight, and skinfold thickness or other anthropometric measurements, as appropriate. Ascertain amount of recent weight loss. Weigh daily or as indicated.	If these measurements fall below minimum standards, client's chief source of stored energy, fat tissue, is depleted.
Assess skin and mucous membranes for pallor, delayed wound healing, and enlarged parotid glands.	Helps in identification of protein-calorie malnutrition, especially when weight and anthropometric measurements are less than normal.
Encourage client to eat high-calorie, nutrient-rich diet, with adequate fluid intake. Provide finger foods and age-appropriate choices. Encourage use of supplements and frequent, smaller meals spaced throughout the day.	Hypermetabolic state and treatment requires increased nutrients and fluids to promote healing and elimination of toxins. Supplements can play an important role in maintaining adequate caloric and protein intake. Note: Early studies regarding eating-related distress indicate there is currently no evidence that people with advanced

(continues on page 958)

**ACTIONS/INTERVENTIONS (continued)****RATIONALE (continued)**

Recommend avoiding processed and grilled meats.	cancer can improve their survival or quality of life by changing what they eat. Therefore, the goal of psycho-social intervention may need to change from optimizing nutritional intake to mitigating weight- and eating-related distress when the focus of treatment and care shifts from achieving cure to optimizing quality of life (Amano et al, 2016; Hopkinson et al, 2006).
Create pleasant dining atmosphere; encourage client to share meals with family and friends.	Processed and grilled/barbecued or smoked meats may contain polycyclic aromatic hydrocarbon carcinogens (Yian, 2015).
Encourage open communication regarding anorexia and cachexia.	Makes mealtime more enjoyable, which may enhance intake. Often a source of emotional distress, especially for SO who wants to feed client frequently. When client refuses to eat, SO may feel rejected or frustrated or that client has "given up."

**Chemotherapy Management NIC**

Adjust diet before and immediately after treatments (e.g., clear, cool liquids; light or bland foods; candied ginger; dry crackers; toast; and carbonated drinks). Offer liquids 1 hour before or 1 hour after meals.	The effectiveness of diet adjustment is individualized in relief of posttherapy nausea. Client must experiment to find best solution and combinations. Avoiding fluids during meals minimizes becoming "full" too quickly.
Control environmental factors, such as strong or noxious odors and noise.	Can trigger nausea and vomiting response.
Avoid overly sweet, fatty, or spicy foods.	May prevent onset or reduce severity of nausea, decrease anorexia, and enable client to increase oral intake.
Encourage use of relaxation techniques, visualization, guided imagery, and moderate exercise before meals.	Psychogenic nausea and vomiting occurring before chemotherapy generally does not respond to antiemetic drugs. Change of treatment environment or client routine on treatment day may be effective.
Identify the client who experiences anticipatory nausea or vomiting, and take appropriate measures.	Individuals respond differently to all medications. First-line antiemetics may not work, requiring alteration in or use of combination drug therapy.
Evaluate effectiveness of antiemetic agents.	Certain therapies, such as antimetabolites, inhibit renewal of epithelial cells lining the gastrointestinal (GI) tract, which may cause changes ranging from mild erythema to severe ulceration with bleeding.
Hematest stools and gastric secretions.	
<b>Collaborative</b>	
Review laboratory studies, as indicated, such as total lymphocyte count, serum transferrin, and albumin or prealbumin.	Helps identify the degree of biochemical imbalance or malnutrition and influences choice of dietary interventions. Note: Anticancer treatments can also alter nutrition studies, so all results must be correlated with the client's clinical status.
Administer medications, as indicated, for example:	
5-HT3 receptor antagonists, such as ondansetron (Zofran), granisetron (Kytril), dolasetron (Anzemet), and palonosetron (Aloxi); NK-1 receptor antagonist aprepitant (Emend); phenothiazines, such as prochlorperazine (Compazine) and thiethylperazine (Torecan); antidopaminergics, such as metoclopramide (Reglan); antihistamines, such as diphenhydramine (Benadryl); and cannabinoids, such as dronabinol (Marinol)	Most antiemetics act to interfere with stimulation of true vomiting center, and chemoreceptor trigger zone agents also act peripherally to inhibit reverse peristalsis. These medications are often prescribed routinely before, during, and after chemotherapy to prevent nausea and vomiting.
Corticosteroids, such as dexamethasone (Decadron); benzodiazepines, such as lorazepam (Ativan); and butyrophenones, such as haloperidol (Haldol) or droperidol (Inapsine)	Combination therapy such as Compazine with Decadron and/or Ativan is often more effective than single agents.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Vitamins, especially A, D, and B <sub>6</sub>	Prevents deficit related to decreased absorption of fat-soluble vitamins. Deficiency of B <sub>6</sub> can contribute to or exacerbate depression, irritability, and neuropathy. Note: Some medical providers recommend avoiding such antioxidants as E and C because they may interfere with chemotherapy and radiation.
Antacids and/or proton pump inhibitors, such as esomeprazole (Nexium), lansoprazole (Prevacid), or pantoprazole (Protonix)	Minimizes gastric irritation, decreases nausea, and reduces risk of mucosal ulceration.
Administer antiemetic on a regular schedule before or during and after administration of antineoplastic agent and radiation, as appropriate.	Nausea and vomiting are frequently the most disabling and psychologically stressful side effects of chemotherapy.
Provide support and psychosocial interventions to deal with WRD and ERD experienced by clients and families.	Psychosocial interventions are beginning to be used to directly deal with eating- and weight-related distress manifestations experienced by 80% of clients with advanced cancer disease (Hopkinson et al, 2013). For many clients, mitigation of distress is likely to be achieved by supporting them in optimizing their nutritional intake within the confines of their small appetite and other obstacles to eating (considered to be a psychosocial intervention) (Hopkinson et al, 2013).
Provide oral care (e.g., doxepin oral rinse, lidocaine-based mouthwash).	Useful in alleviating pain associated with radiotherapy-related oral mucositis (Mulcahy, 2016).

**Nutrition Therapy NIC**

Refer to dietitian or nutritional support team.

Insert and maintain nasogastric (NG) or feeding tube for enteric feedings or central line for total parenteral nutrition (TPN), if indicated.

Provides for specific dietary plan to meet individual needs and reduce problems associated with protein or calorie malnutrition and micronutrient deficiencies.

In the presence of severe malnutrition, when the client is not currently terminal (e.g., loss of 25% to 30% body weight), or if client has been nothing-by-mouth status (NPO) for 5 days and is unlikely to be able to eat for another week, tube feeding or TPN may be necessary to meet nutritional needs.

**NURSING DIAGNOSIS: risk for deficient Fluid Volume****Possibly Evidenced By**

Excessive losses through normal routes—vomiting, diarrhea; abnormal routes—indwelling tubes, wounds, fistulas

Factors influencing fluid needs (e.g., hypermetabolic state)

Deviations affecting intake of fluids (e.g., nausea)

**Desired Outcomes/Evaluation Criteria—Client Will****Hydration NOC**

Display adequate fluid balance as evidenced by stable vital signs, moist mucous membranes, good skin turgor, prompt capillary refill, and individually adequate urinary output.

**ACTIONS/INTERVENTIONS****RATIONALE****Fluid/Electrolyte Management NIC****Independent**

Monitor intake and output (I&O) and specific gravity. Include all output sources, such as emesis, diarrhea, or draining wounds, weigh continence briefs/diapers. Calculate 24-hour balance.

Continued negative fluid balance, decreasing renal output, and concentration of urine suggest developing dehydration and need for increased fluid replacement.

Weigh, as indicated.

Sensitive measurement of fluctuations in fluid balance.

(continues on page 960)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Monitor vital signs. Evaluate peripheral pulses and capillary refill.	Reflects adequacy of circulating volume.
Assess skin turgor and moisture of mucous membranes. Note reports of thirst.	Indirect indicators of hydration status and degree of deficit.
Encourage increased fluid intake as individually appropriate and tolerated.	Assists in maintenance of fluid requirements and reduces risk of harmful side effects such as hemorrhagic cystitis in client receiving cyclophosphamide (Cytoxan).
Offer fluids on regular basis to infants, young children, and the elderly.	The very young and the elderly may not sense or be able to report thirst.
Observe for bleeding tendencies, such as oozing from mucous membranes or puncture sites and presence of ecchymosis or petechiae.	Early identification of problems that may occur as a result of cancer and/or therapies allows for prompt intervention.
Minimize venipunctures such as combining IV starts with blood draws. Encourage client to consider central or peripheral venous catheter placement.	Reduces potential for hemorrhage and infection associated with repeated venous puncture.
Avoid trauma and apply pressure to puncture sites.	Reduces potential for bleeding and hematoma formation.
<b>Collaborative</b>	
Provide IV fluids as indicated.	Given for general hydration and to dilute antineoplastic drugs and reduce adverse side effects—nausea, vomiting, or nephrotoxicity.
Administer antiemetic therapy. (Refer to ND: imbalanced Nutrition: less than body requirements.)	Alleviation of nausea and vomiting decreases gastric losses and allows for increased oral intake.
Monitor laboratory studies, such as CBC, electrolytes, and serum albumin.	Provides information about level of hydration and corresponding deficits. Note: Malnutrition and effects of decreased albumin levels potentiate fluid shifts or edema formation.
Administer transfusions, as indicated:	
RBCs	May be needed to restore blood count and prevent manifestations of anemia often present in cancer clients, such as tachycardia, tachypnea, dizziness, and weakness.
Platelets	Thrombocytopenia may occur as a side effect of chemotherapy, radiation, or cancer process, increasing the risk of bleeding from mucous membranes and other body sites. Spontaneous bleeding may occur with platelet count of 5000.
Avoid use of aspirin, gastric irritants, platelet inhibitors, or herbs such as ginseng, green tea, garlic, ginger, ginkgo, or willow bark.	These substances can negatively affect clotting mechanism and/or potentiate risk of bleeding.

## NURSING DIAGNOSIS: Fatigue

### May Be Related To

Anemia; malnutrition  
Anxiety; depression  
[Altered body chemistry—side effects of pain and other medications, chemotherapy, radiation therapy, biotherapy]

### Possibly Evidenced By

Insufficient energy; tiredness; impaired ability to maintain usual routines or physical activities  
Decreased performance, alteration in concentration  
Lethargy; listlessness; disinterest in surroundings

### Desired Outcomes/Evaluation Criteria—Client Will

#### Endurance NOC

Report improved sense of energy.  
Perform ADLs and participate in desired activities at level of ability.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Energy Management NIC</b>	
<b>Independent</b>	
Have client rate fatigue, using a numeric scale, such as the Multidimensional Fatigue Inventory (MFI), if possible, and the time of day when it is most severe.	Helps in developing a plan for managing CRF to improve client's quality of life (Horneber et al, 2012).
Plan care to allow for rest and uninterrupted sleep periods. Schedule activities for periods when client has most energy. Involve client and SO in schedule planning.	Frequent rest periods and/or naps are needed to conserve and restore energy. Planning will allow client to be active during times when energy level is higher, which may restore a feeling of well-being and a sense of control.
Establish realistic activity goals with client.	Provides for a sense of control and feelings of accomplishment.
Assist with self-care needs when indicated; keep bed in low position and pathways clear of furniture and assist with ambulation.	Weakness may make ADLs difficult to complete or place the client at risk for injury during activities.
Encourage client to do whatever possible, such as self-bathing, sitting up in chair, and walking. Increase activity level as individual is able.	Enhances strength and stamina and enables client to become more active without undue fatigue.
Encourage aerobic exercise, as client is able, with goal of 30 minutes per day.	Aerobic exercise minimizes fatigue, increases strength and stamina, and stimulates release of natural endorphins, which promotes sense of well-being.
Monitor physiological response to activity, such as changes in BP or heart and respiratory rate.	Tolerance varies greatly depending on the stage of the disease process, nutrition state, fluid balance, and reaction to therapeutic regimen.
Perform pain assessment and provide pain management.	Poorly managed cancer pain can contribute to fatigue.
Encourage nutritional intake. (Refer to ND: imbalanced Nutrition: less than body requirements.)	Adequate intake and use of nutrients is necessary to meet energy needs and build energy reserves for activity.
Encourage adequate fluid intake. (Refer to ND: risk for deficient Fluid Volume.)	Prevents dehydration, which increases fatigue.
<b>Collaborative</b>	
Provide supplemental oxygen, as indicated.	Presence of anemia or hypoxemia reduces O <sub>2</sub> available for cellular uptake and contributes to fatigue.
Refer to physical and occupational therapy.	Programmed daily exercises and activities help client maintain or increase strength and muscle tone and enhance sense of well-being. Use of adaptive devices may help conserve energy.

## NURSING DIAGNOSIS: risk for Infection

### Possibly Evidenced By

Alteration in skin integrity; immunosuppression, pharmaceutical agents  
Malnutrition; chronic illness  
Invasive procedure

### Desired Outcomes/Evaluation Criteria—Client Will

#### Infection Severity NOC

Remain afebrile.  
Achieve timely healing, as appropriate.

#### Knowledge: Infection Control NOC

Identify and participate in interventions to prevent and reduce risk of infection.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Infection Protection NIC</b>	
<i>Independent</i>	
Promote good handwashing procedures by staff and visitors. Screen and limit visitors who may have infections.	Protects client from sources of infection, such as visitors and staff who may have an upper respiratory infection (URI).
Emphasize personal hygiene.	Limits potential sources of infection.
Monitor temperature.	Temperature elevation may occur, if not masked by corticosteroids or anti-inflammatory drugs, because of various factors, including chemotherapy side effects, disease process, or infection. Early identification of infectious process enables appropriate therapy to be started promptly.
Encourage fluids. (Refer to ND: risk for deficient Fluid Volume.)	Adequate fluid intake enhances immune system and aids natural defense mechanisms.
Assess all systems (e.g., skin, respiratory, genitourinary) for signs and symptoms of infection on a continual basis.	Early recognition and intervention may prevent progression to more serious situation such as sepsis.
Reposition frequently; keep linens dry and wrinkle-free.	Reduces pressure and irritation to tissues and may prevent skin breakdown.
Promote adequate rest and exercise periods.	Limits fatigue, yet encourages sufficient movement to prevent stasis complications—pneumonia, pressure injury, or thrombus formation.
Stress importance of good oral hygiene.	Development of stomatitis increases risk of infection and secondary overgrowth.
Avoid or limit invasive procedures, as possible. Adhere to aseptic techniques.	Reduces risk of contamination and limits portal of entry for infectious agents.
<i>Collaborative</i>	
Monitor CBC with differential WBC and granulocyte count and platelets, as indicated.	Bone marrow activity may be inhibited by effects of chemotherapy, the disease state, or radiation therapy. Monitoring status of myelosuppression is important for preventing further complications, such as infection, anemia, or hemorrhage, and scheduling drug delivery. Note: The nadir is usually seen 7 to 10 days after administration of chemotherapy.
Obtain cultures, as indicated.	Identifies causative organism(s) and appropriate therapy.
Administer antibiotics, as indicated. Provide antibiotics within 1 hour, as ordered for neutropenic sepsis (Davis, 2013).	May be used to treat identified infection or given prophylactically in immunocompromised client.

### NURSING DIAGNOSIS: risk for impaired oral Mucous Membrane

#### Possibly Evidenced By

Treatment regimen; chemotherapy; radiation therapy; immunosuppression  
Nil by mouth (NPO) for more than 24 hours; dehydration; malnutrition

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Oral Health NOC

Display intact mucous membranes, which are pink, moist, and free of inflammation or ulcerations.

##### Self-Care: Oral Hygiene NOC

Verbalize understanding of causative factors.  
Demonstrate techniques to maintain or restore integrity of oral mucosa.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Oral Health Maintenance NIC</b>	
<i>Independent</i>	
Assess dental health and oral hygiene periodically.	Identifies prophylactic treatment needs before initiation of chemotherapy or radiation and provides baseline data of current oral health for future comparison.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Encourage client to assess oral cavity daily, noting changes in mucous membrane integrity. Note reports of burning in the mouth, changes in voice quality, ability to swallow, sense of taste, development of thick saliva, or blood-tinged emesis.	Stomatitis generally occurs 7 to 14 days after treatment begins, but signs may be seen as early as day 3 or 4, especially if there are any preexisting oral problems. The range of response extends from mild erythema to severe ulceration and may extend the length of the GI tract, which can be very painful, can inhibit oral intake, and is potentially life-threatening. Early identification enables prompt treatment.
Discuss with client areas needing improvement and demonstrate methods for good oral care.	Good care is critical during treatment to control stomatitis complications.
Initiate and recommend oral hygiene program to include the following:	Products containing alcohol or phenol may exacerbate mucous membrane dryness or irritation.
Avoidance of commercial mouthwashes and lemon or glycerin swabs	May be soothing to the membranes. Rinsing before meals may improve the client's sense of taste. Rinsing after meals and at bedtime dilutes oral acids and relieves xerostomia.
Use of mouthwash made from warm water with salt and baking soda; diluted solution of hydrogen peroxide may be used for bleeding or infected tissue	Prevents trauma to delicate, fragile tissues. Note: Toothbrush should be changed every month.
Brushing with soft toothbrush or foam swab	Removes food particles that can promote bacterial growth. Note: Water under pressure has the potential to injure gums and force bacteria under gum line.
Flossing gently or use WaterPik™ cautiously	Promotes comfort and prevents drying and cracking of tissues.
Keeping lips moist with lip gloss or balm, K-Y Jelly, Chapstick	Stimulates secretions and provides moisture to maintain integrity of mucous membranes, especially in presence of dehydration and reduced saliva production.
Use of mints, other hard candy, or artificial saliva (Ora-Lube, Salivart), as indicated	Severe stomatitis may interfere with nutritional and fluid intake, leading to negative nitrogen balance or dehydration. Dietary modifications may make foods easier to swallow and may feel soothing.
Instruct regarding dietary changes, such as avoiding hot or spicy foods and acidic juices; suggest use of straw; ingest soft or blenderized foods, popsicles, and ice cream, as tolerated.	Adequate hydration helps keep mucous membranes moist, preventing drying and cracking.
Encourage fluid intake as individually tolerated.	May cause further irritation and dryness of mucous membranes.
Discuss effects of smoking and alcohol intake, if indicated, and address concerns.	Early recognition provides opportunity for prompt treatment.
Monitor for, and explain to client, signs of oral super infection such as thrush.	
<b>Collaborative</b>	
Refer to dentist before initiating chemotherapy or head and neck radiation.	Prophylactic examination and repair work before therapy reduce risk of infection.
Culture suspicious oral lesions.	Identifies organism(s) responsible for oral infections and suggests appropriate drug therapy.
Administer medications, as indicated, for example:	
Analgesic rinses, such as GelClair, mixture of Koatin, pectin, diphenhydramine (Benadryl), and topical lidocaine (Xylocaine)	Aggressive analgesia program may be required to relieve intense pain. Note: Rinse should be used as a swish-and-spit rather than a gargle, which could anesthetize client's gag reflex.
Antifungal mouthwash preparation, such as nystatin (Mycostatin) and antibacterial Biotane	May be needed to treat or prevent secondary oral infections, such as <i>Candida</i> , <i>Pseudomonas</i> , and <i>herpes simplex</i> .
Antinausea agents, such as dolasetron (Anzemet), granisetron (Kytril)	When given before beginning mouth care regimen, may prevent nausea associated with oral stimulation, especially when client is receiving a chemotherapy regimen.
Opioid analgesics, such as hydromorphone (Dilaudid) or morphine	May be required for acute episodes of moderate to severe oral pain.

## NURSING DIAGNOSIS: risk for impaired Skin/Tissue Integrity

### Possibly Evidenced By

Pharmaceutical agent (e.g., chemotherapy); radiation  
Immunodeficiency  
Imbalanced nutritional state/inadequate nutrition (e.g., malnutrition; anemia)

### Desired Outcomes/Evaluation Criteria—Client Will

#### Risk Control NOC

Identify interventions appropriate for specific condition.  
Participate in techniques to prevent complications and promote healing, as appropriate.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Chemotherapy [or] Radiation Therapy Management NIC</b> <i>Independent</i>	
Assess skin frequently for side effects of cancer therapy; note breakdown and delayed wound healing. Emphasize importance of reporting open areas to caregiver.	A reddening and/or tanning effect called radiation dermatitis may develop within the field of radiation. Dry desquamation with dryness and pruritus, moist desquamation with blistering, ulceration, hair loss, and loss of dermis and sweat glands may also be noted. In addition, skin reactions—allergic rashes, hyperpigmentation, pruritus, increased risk of sunburn, acne-like skin eruptions, and alopecia—may occur with some chemotherapy agents.
Bathe with lukewarm water and mild soap.	Maintains cleanliness without irritating the skin.
Encourage client to avoid vigorous rubbing and scratching and to pat skin dry instead of rubbing.	Helps prevent skin friction or trauma to sensitive tissues.
Turn or reposition frequently.	Promotes circulation and prevents undue pressure on skin and underlying tissues.
Review skin care protocol for client receiving radiation therapy:  Avoid rubbing or use of soap, lotions, creams, ointments, powders, or deodorants on area; avoid applying heat or attempting to wash off marks or tattoos placed on skin to pinpoint location for radiation therapy.	Designed to minimize trauma to area of radiation therapy.  These factors can potentiate or otherwise interfere with radiation delivery and may actually increase reaction.
Recommend wearing soft, loose cotton clothing; have female client avoid wearing bra if it creates pressure.	Skin is very sensitive during and after treatment, and all irritation should be avoided to prevent dermal injury.
Apply cornstarch, Aquaphor, Lubriderm, Eucerin, or other water-soluble moisturizing gel to area twice daily or more frequently, as needed.	Helps control dampness or pruritus. Maintenance care is required until skin and tissues have regenerated and are back to normal.
Encourage liberal use of sunblock and breathable, protective clothing.	Protects skin from ultraviolet rays and reduces risk of recall reactions.
Review skin care protocol for client receiving chemotherapy:  Use appropriate peripheral or central venous catheter, dilute anticancer drug per protocol, and ascertain that IV is infusing well.	Reduces risk of tissue irritation or extravasation of agent into tissues.
Instruct client to notify caregiver promptly of discomfort at IV insertion site.	Development of irritation indicates need for alteration of rate or dilution of chemotherapy and/or change of IV site to prevent more serious reaction.
Assess skin, IV site, and vein for erythema, edema, tenderness, weltlike patches, itching, burning, swelling, soreness, and blisters progressing to ulceration or tissue necrosis.	Presence of phlebitis or extravasation requires immediate discontinuation of antineoplastic agent and medical intervention. Note: Vein flare, a localized reaction, may resolve without intervention based on individual reaction.
Wash skin immediately with soap and water if antineoplastic agents are spilled on unprotected skin of client or caregiver.	Dilutes drug to reduce risk of skin irritation and chemical burn.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Advise clients receiving 5-fluorouracil (5-FU) and methotrexate to avoid sun exposure. Withhold methotrexate if sunburn is present.	Sun can cause exacerbation of burn spotting, a side effect of 5-FU, or can cause a red “flash” area with methotrexate, which can exacerbate drug’s effect.
Review expected dermatological side effects seen with chemotherapy, such as rash, hyperpigmentation, acne-like eruptions, and peeling of skin on palms.	Anticipatory guidance helps decrease concern if side effects do occur.
Inform client that if alopecia occurs, hair could grow back after completion of chemotherapy but may or may not grow back after radiation therapy.	Anticipatory guidance may help adjustment to, or preparation for, baldness. Men are often as sensitive to hair loss as women. Radiation’s effect on hair follicles may be permanent, depending on radiation dosage.
<b>Collaborative</b>	
Administer appropriate antidote if extravasation of IV should occur, for example:	
Dimethyl sulfoxide (DMSO)	Some studies suggest benefit with topical DMSO for mitomycin and doxorubicin (Adriamycin). Note: Injection of diphenhydramine (Benadryl) may relieve urticaria or vein flare.
Hyaluronidase (Wydase)	Injected subcutaneously for vincristine (Oncovin), vinblastine (Velban), etoposide (VP16), vindesine (Eldisine), vinorelbine (Navelbine), teniposide (Vm26), or paclitaxel (Taxol) infiltration.
Thiosulfate	Injected subcutaneously for nitrogen mustard and large amounts, greater than 20 mL, of concentrated cisplatin.
Apply ice pack or warm compresses per protocol.	Controversial intervention depends on type of agent used. Ice restricts blood flow, keeping drug localized, whereas heat enhances dispersion of neoplastic drug or antidote, minimizing tissue damage.

### NURSING DIAGNOSIS: risk for Constipation/Diarrhea

#### Possibly Evidenced By

Eating habit change; insufficient fiber/fluid intake  
Pharmaceutical agent/treatment regimen; radiation  
Gastrointestinal inflammation; malabsorption

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Bowel Elimination NOC

Maintain usual bowel consistency and pattern.  
Verbalize understanding of factors and appropriate interventions or solutions related to individual situation.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Bowel Management NIC</b>	
<i>Independent</i>	
Ascertain usual elimination habits.	Data required as baseline for future evaluation of therapeutic needs and effectiveness.
Assess bowel sounds and monitor and record bowel movements (BMs), including frequency and consistency—particularly during first 3 to 5 days of vinca alkaloid therapy and when receiving pain and/or nausea medications.	Defines problem—diarrhea or constipation. Note: Constipation is one of the earliest manifestations of neurotoxicity.
Monitor I&O and weight.	Dehydration, weight loss, and electrolyte imbalance are complications of diarrhea. Inadequate fluid intake may potentiate constipation.

(continues on page 966)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Encourage adequate fluid intake, increased fiber in diet, and regular exercise.	May reduce potential for constipation by improving stool consistency and stimulating peristalsis; can prevent dehydration associated with diarrhea.
Provide small, frequent meals of foods low in residue if not contraindicated, maintaining needed protein and carbohydrates, such as eggs, cooked cereal (oatmeal), or bland cooked vegetables.	Reduces gastric irritation. Use of low-fiber foods can decrease irritability and provide bowel rest when diarrhea present.
Adjust diet as appropriate—avoid foods high in fat, such as butter, fried foods, and nuts; foods with high-fiber content and those known to cause diarrhea or gas, including cabbage, baked beans, and chili; food or fluids high in caffeine; or extremely hot or cold food and fluids.	GI stimulants that may increase gastric motility and frequency of stools.
Check for impaction if client has not had BM in 3 days or if abdominal distention, cramping, and headache are present.	Further interventions and alternative bowel care may be needed.
<b>Collaborative</b>	
Monitor laboratory studies, such as electrolytes, as indicated. Administer the following, as indicated:	Electrolyte imbalances may be the result of, or contribute to, altered GI function.
IV fluids	Prevents dehydration and dilutes chemotherapy agents to diminish side effects.
Antidiarrheal agents	May be indicated to control severe diarrhea.
Stool softeners and laxatives	Prophylactic use may prevent further complications in some clients, such as those who will receive vinca alkaloid, have poor bowel pattern before treatment, or have decreased motility. Note: Enemas and suppositories are to be avoided when possible as they increase the potential for infection and are uncomfortable and unpleasant for the client.

### NURSING DIAGNOSIS: risk for Sexual Dysfunction

#### Possibly Evidenced By

Alteration in body function or structure (e.g., disease process, drugs, surgery, radiation)  
Absence of privacy or significant other (SO)

#### Desired Outcomes/Evaluation Criteria—Client Will

#### Sexual Functioning NOC

Verbalize understanding of effects of cancer and therapeutic regimen on sexuality and measures to correct or deal with problems.  
Maintain sexual activity at a desired level, as possible.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Sexual Counseling NIC</b>	
<b>Independent</b>	
Discuss with client and SO the nature of sexuality and reactions when it is altered or threatened. Provide information about normality of these problems and that many people find it helpful to seek assistance with adaptation process.	Acknowledges legitimacy of the problem. Sexuality encompasses the way men and women view themselves as individuals and how they relate between and among themselves in every area of life.
Advise client of side effects of prescribed cancer treatment that are known to affect sexuality.	Anticipatory guidance can help client and SO begin the process of adaptation to new state.
Provide private time for hospitalized client. Knock on door and receive permission from client and SO before entering.	Sexual needs do not end because the client is hospitalized/in a facility. Intimacy needs continue, and an open and accepting attitude for the expression of those needs is essential.
<b>Collaborative</b>	
Refer to sex therapist, as indicated.	May require additional assistance in dealing with situation.

**NURSING DIAGNOSIS:** **risk for interrupted Family Processes****Possibly Evidenced By**

Situational crises; shift in health status of a family member  
Shift in family roles; change in family finances

**Desired Outcomes/Evaluation Criteria—Family Will****Family Resiliency NOC**

Express feelings freely.  
Demonstrate individual involvement in problem-solving process directed at appropriate solutions for the situation.  
Encourage and allow member who is ill to handle situation in own way.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Family Process Maintenance NIC</b>	
<i>Independent</i>	
Note components of family, presence of extended family, and others, including friends and neighbors.	Helps client and caregiver know who is available to assist with care and provide respite and support.
Identify patterns of communication in family and patterns of interaction between family members.	Provides information about effectiveness of communication and identifies problems that may interfere with family's ability to assist client and adjust positively to diagnosis and treatment of cancer.
Assess role expectations of family members and encourage discussion about them.	Each person may see the situation in own individual manner, and clear identification and sharing of these expectations promote understanding.
Assess energy direction: Are efforts at resolution or problem-solving purposeful or scattered?	Provides clues about interventions that may be appropriate to assist client and family in directing energies in a more effective manner.
Note cultural and religious beliefs.	Affects client and SO reaction and adjustment to diagnosis, treatment, and outcome of cancer.
Listen for expressions of helplessness.	Helpless feelings may contribute to difficulty adjusting to diagnosis of cancer and cooperating with treatment regimen.
Deal with family members in a warm, caring, respectful way. Provide verbal and written information and reinforce, as necessary.	Provides feelings of empathy and promotes individual's sense of worth and competence in ability to handle current situation.
Encourage appropriate expressions of anger avoid reacting negatively to them.	Feelings of anger are to be expected when individuals are dealing with the difficult, potentially fatal illness of cancer. Appropriate expression enhances dealing with the stages of the grieving process.
Acknowledge difficulties of the situation, such as the diagnosis and treatment of cancer or possibility of death.	Communicates acceptance of the reality the client and family are facing.
Identify and encourage use of previously successful coping behaviors.	Most people have developed effective coping skills that can be useful in dealing with current situation.
Emphasize importance of continuous open dialogue between family members.	Promotes understanding and assists family members to maintain clear communication and resolve problems effectively.
<i>Collaborative</i>	
Refer to support groups, clergy, and family therapy, as indicated.	May need additional assistance to resolve problems of disorganization that may accompany diagnosis of potentially terminal illness.

**NURSING DIAGNOSIS:** **readiness for enhanced Health Management****Possibly Evidenced By**

Expresses desire to enhance management of illness/symptoms, prescribed regimens  
Expresses desire to enhance choices of daily living for meeting goals

(continues on page 968)

**NURSING DIAGNOSIS:** **readiness for enhanced Health Management** (continued)**Desired Outcomes/Evaluation Criteria—Client Will****Knowledge: Cancer Management NOC**

Verbalize accurate information about diagnosis, prognosis, and potential complications at own level of readiness.  
Verbalize understanding of therapeutic needs.  
Correctly perform necessary procedures and explain reasons for the actions.  
Initiate necessary lifestyle changes and participate in treatment regimen.  
Identify and use available resources appropriately.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Teaching: Disease Process NIC</b> <i>Independent</i> Review with client and SO understanding of specific diagnosis, treatment alternatives, and future expectations.	Validates current level of understanding, identifies learning needs, and provides knowledge base from which client can make informed decisions.
Determine client's perception of cancer and cancer treatment(s). Ask about client's own or previous experience or experience with other people who have, or had, cancer.	Aids in identification of ideas, attitudes, fears, misconceptions, and gaps in knowledge about cancer.
Provide clear, accurate information in a factual but sensitive manner. Answer questions specifically, but do not bombard with nonessential details.  <b>Use age-appropriate materials such as puppets for children.</b>	Helps with adjustment to the diagnosis of cancer by providing needed information along with time to absorb it. Note: Rate and method of giving information may need to be altered to decrease client's anxiety and enhance ability to assimilate information.
Provide anticipatory guidance with client and SO regarding treatment protocol, length of therapy, expected results, and possible side effects. Be honest with client.	Client has the "right to know" and participate in decisions. Accurate and concise information helps to dispel fears and anxiety, helps clarify the expected routine, and enables client to maintain some degree of control.
Provide written materials about cancer, treatment, and available support systems.	Anxiety and preoccupation with thoughts about life and death often interfere with client's ability to assimilate adequate information. Written materials provide reinforcement and clarification about information as client needs it.
Ask client for verbal feedback, and correct misconceptions about individual's type of cancer and treatment choices.	Misconceptions about cancer may be more disturbing than facts and can interfere with treatments or delay healing.
Review specific medication regimen and use of over-the-counter (OTC) drugs/supplements, herbals.	Enhances ability to manage self-care and avoid potential complications and drug reactions or interactions.
Outline normally expected limitations, if any, on ADLs, including difficulty cooking meals when nauseated or fatigued and loss of work time because of effects of treatments.	Enables client and SO to begin to put limitations into perspective and plan for, or adapt, as indicated.
Address specific home-care needs such as ability to live alone, perform necessary treatments or procedures, and acquire supplies.	Provides information regarding changes that may be needed in current plan of care to meet therapeutic needs.
Do predischarge home evaluation, as indicated.	Aids in transition to home setting by providing information about needed changes in physical layout and the acquisition of needed supplies.
Refer to community resources, as indicated, such as social services, home health agencies, Meals on Wheels, local chapter of American Cancer Society, respite care, hospice center, or other services.	Promotes competent self-care and optimal independence. Maintains client in home or desired setting.
Review with client and SO the importance of maintaining optimal nutritional status.	Promotes well-being, facilitates recovery, and is critical in enabling the client to tolerate treatments.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Encourage diet variations and experimentation in meal planning and food preparation, such as cooking with sweet juices or wine and serving foods cold or at room temperature, as appropriate.	Creativity may enhance flavor and intake, especially when protein foods taste bitter.
Recommend cookbooks that are designed for cancer clients.	Helps provide specific menu and recipe ideas.
Recommend increased fluid intake and fiber in diet, as well as routine exercise.	Improves consistency of stool and stimulates peristalsis.
Instruct client to assess oral mucous membranes routinely, noting erythema or ulceration.	Early recognition of problems promotes early intervention, minimizing complications that may impair oral intake and provide avenue for systemic infection.
Advise client concerning skin and hair care: avoid harsh shampoos, hair dyes, permanents, salt water, and chlorinated water; avoid exposure to strong wind and extreme heat or cold; avoid sun exposure to target area for 1 year after end of radiation treatments; and regularly apply sunblock (SPF 15 or greater).	Prevents additional hair damage and skin irritation and may prevent recall reactions.
<b>Collaborative</b>	
Initiate medical and support referrals for smoking or alcohol cessation program if client desires.	Decreases irritation to mucous membranes, enhances healing, and promotes general well-being.
Review signs and symptoms requiring medical evaluation, such as infection, delayed healing, drug reactions, and increased pain, or swelling of face or hands and arms that may worsen when lying down, dyspnea, cough, headache, and visual disturbances suggestive of SVCS.	Early identification and treatment may limit severity of complications. Note: The use of central venous access devices for various therapies—chemotherapy, TPN, or antibiotic administration—may cause local vein trauma leading to SVCS days, months, or even years after catheter insertion.
Stress importance of continuing medical follow-up.	Provides ongoing monitoring of progression or resolution of disease process and opportunity for timely diagnosis and treatment of complications and early detection of second malignancies. Note: Some complications can develop long after therapy is completed, such as pathological fractures, radiation cystitis, or pneumonitis. Periodic thyroid function tests are indicated for clients with radiation to the neck and upper chest because hypothyroidism may develop.
Encourage periodic review of advance directives. Promote inclusion of family and SO in decision-making process.	Client, family, and SO need to reevaluate choices as condition changes and treatment options become available or are exhausted.
Refer to community palliative/respite care or hospice if needed.	Palliative care will address pain control, long-term support, and end-of-life care if indicated (Leadbeater, 2013).

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition and presence of complications, personal resources, and life responsibilities)

**In addition to Potential Considerations in specific plans of care such as leukemia, mastectomy:**

- **ineffective Coping**—situational crises; uncertainty; high degree of threat
- **Self-Care deficit/Impaired Home Maintenance**—disease; pain, discomfort; weakness, impaired functioning; fatigue; insufficient finances; unfamiliarity with neighborhood resources; inadequate support systems
- **risk for caregiver Role Strain**—illness severity of care receiver; presence of situational stressors that normally affect families (e.g., crisis, economic vulnerability); unpredictable illness course; amount/complexity of caregiving tasks
- **acute/chronic Pain**—physical agents (e.g., disease process, compression or destruction of nerve tissue, infiltration of nerves or their vascular supply, obstruction of a nerve pathway, inflammation)
- **ineffective Health Management**—complexity of therapeutic regimen; economic difficulties; decisional conflicts; perceived barriers; powerlessness; social support deficit

# PALLIATIVE/END-OF-LIFE CARE—HOSPICE

**I. Purpose**—Palliative and hospice medicine provide holistic care and support by employing an interdisciplinary team approach that can address the physical, social, emotional, and spiritual needs of the client and family (Bodtke & Ligon, 2016). Palliative care focuses on improving quality of life of individuals and their families facing the problems associated with life-threatening illness (World Health Organization [WHO], n.d.) whose life expectancy is usually longer than 6 months. Hospice care focuses on comfort and quality of life, rather than curative treatments by providing medical treatment of pain and other distressing symptoms associated with serious or life-threatening or progressive illness, but it does not prolong life (Martinez & Berry, 2015). *Note:* Pain relief and other measures intended to improve quality of life and mood may result in extending life (Temel et al., 2010), and on occasion, some clients may improve enough to “graduate” from hospice care for a period of time.

## II. Indications

- a. Palliative care (Martinez & Berry, 2015)
  - i. Terminally ill and need assistance with goals of care
  - ii. Continue to receive active treatment for an incurable illness but who can benefit from support services and symptom management
  - iii.  Children with severe congenital anomalies, severe or life-threatening illness, but are considered to be far from the terminal stage
- b. Hospice (Centers for Medicare and Medicaid Services, 2017)
  - i. Hospice physician and primary care physician must both certify terminal illness.
  - ii. Life expectancy of 6 months or less regardless of age, sex, or race
- c. Care of the dying person encompasses several dimensions (Malloy et al, 2008)
  - i. Management of pain and other physical symptoms—nausea, vomiting, fatigue, anorexia, functional decline
  - ii. Psychological and spiritual support
    - 1. Provide client and family the opportunity to consider the meaning of their lives.
    - 2. Encourage participation in making plans and shaping the course of their living while preparing for death.
  - iii. Bereavement support after death for family

## III. Trajectories of Death Appropriate for Hospice Care (Glaser & Strauss, 1968; Lunney, 2007)

- a. Steady decline, short terminal phase, as may occur with certain cancers
- b. Slow decline with periodic crises and then death, as may occur with chronic obstructive pulmonary disease (COPD), heart or kidney failure
- c. Lingering, expected death as expected in frail elderly, dementias, stroke, Parkinson’s disease

## IV. Barriers to Using Palliative/Hospice Services (Malloy et al, 2008)

- a. Influence of managed care on end-of-life care
  - i. Lack of understanding of hospice goals and services provided
  - ii. Delay in referral to services (including physician discomfort with end-of-life conversations, fear of depriving client of hope, or causing harm by failing to do something [McAtee & Wellbery, 2013])
- b. Client’s or family member’s denial or avoidance of death; negative perception of hospice (e.g., belief one is giving up; perception that care is being rationed [McAtee & Wellbery, 2013])
- c. Access to care
  - i. Limitations of insurance coverage
  - ii. Medicare payment source requires care be provided by a Medicare-certified hospice program.
- d. Lack of continuity of care across care settings
- e. Caregiver fatigue (psychological and physical) that can compromise the care provided in the home

## V. Statistics (National Hospice and Palliative Care Organization [NHPCO], 2016)

- a. Program availability: in 2012, there were approximately 5800 operational hospice programs in all 50 states, District of Columbia, Puerto Rico, Guam, and U.S. Virgin Islands (Martinez & Berry, 2015). In 2014, the number increased to approximately 6100 programs.
- b. Mortality: There were 2.7 million deaths in the United States in 2015 (CDC, 2017), with an estimated 1.38 million individuals receiving hospice services (NHPCO, 2016).
- c. Cost: In 2015, Medicare expenditures for hospice services were \$15.9 billion (NHPCO, 2016).

## G L O S S A R Y

**Advance directives:** Used to give other people, including healthcare providers, information about client’s wishes for medical care at a time when client is not physically or mentally able to speak for self. The most common types of advance directives are the living will and the durable power of attorney for healthcare.

**End-of-life care:** General term that refers to the comprehensive care given in the advanced or terminal stages of illness.

**Holistic care:** Philosophy of care that is based on healing the whole person; of living and being that is grounded in caring, relationship, and interconnectedness (Klebanoff, 2013).

**Hospice care:** Type of care designed to help clients and their families during the final stages of a terminal illness. Hospice treatment is concentrated primarily on maintaining comfort.

**Locus of control:** The site of control in an individual—internal or external.

**Mindfulness:** Method of staying in the moment.

**Palliative care:** Philosophy of care with the goal of improving the quality of life of clients and their families facing life-threatening illness, through the prevention and relief from suffering. This type of care can encompass treatment of disease processes; provides more than comfort care.

**CARE SETTING**

Although much of the care of the dying is still provided by nurses in hospitals (primarily in oncology and critical care areas), palliative care is generally community based. Hospice care is most common in the home, assisted living, extended-care facilities, or hospice inpatient units.

**RELATED CONCERNS**

Cancer, general considerations, page 945  
Extended/long-term care, page 896  
Psychosocial aspects of care, page 835

**CLIENT ASSESSMENT DATABASE**

Data depend on underlying life-limiting condition, involvement of other body systems, and progression of disease/stage of dying process. Refer to care plan(s) reflecting underlying pathology of condition for specific assessments related to that condition.

**DIAGNOSTIC DIVISION  
MAY REPORT****MAY EXHIBIT****ACTIVITY/REST**

- Fatigue
- General weakness
- Sleep disturbances

**ELIMINATION**

- Abdominal discomfort

***End stage:***

- Constipation (effect of opioids, decreased fluids)
- Dark urine, oliguria

**EGO INTEGRITY**

- Inability to care for self and decision to accept hospice services
- Feelings of helplessness, hopelessness, sorrow, anger; choked feelings
- Fear of the dying process, loss of physical and/or mental abilities
- Concern about impact of death on significant other (SO) and family; difficulty coping—client and/or family
- Inner conflict about beliefs, meaning of life and death; moral distress
- Financial concerns, lack of preparation (e.g., will, power of attorney, funeral)

- Deep sadness, crying, anxiety
- Apathy, social isolation, withdrawal
- Grieving
- Spiritual distress

**FOOD/FLUID**

- Decreasing appetite
- Nausea
- Anorexia

- Weight loss
- Decreased muscle mass, subcutaneous fat
- Poor skin turgor, dry mucous membranes
- Difficulty swallowing

**NEUROLOGICAL**

- ***End stage:***
- Decreasing level of consciousness (LOC)
- Agitation, restlessness
- Terminal delirium

**PAIN/DISCOMFORT**

- Acute or chronic pain

- Muscle tension, restlessness
- Facial grimacing

**RESPIRATION**

- ***End stage:***
- Adventitious breath sounds—rhonchi, wheezes
- Abnormal breathing patterns

(continues on page 972)

**CLIENT ASSESSMENT DATABASE (contd.)****MAY REPORT (continued)****MAY EXHIBIT (continued)****SAFETY**

- Erythema over body prominences
- Skin breakdown, pressure injuries
- Perineal infection—candidiasis

**SOCIAL INTERACTION**

- Apprehension about caregiver's ability to provide care
- Changes in family roles and usual patterns of responsibility
- Loneliness
- Deep sadness
- Apathy, withdrawal

- Altered communication pattern
- Difficulty adapting to changes imposed by condition and dying process
- Family coping concerns

**NURSING PRIORITIES**

1. Control pain.
2. Prevent or manage complications.
3. Maintain quality of life as possible.

4. Plans in place to meet client and family last wishes such as care setting, advance directives, will, and funeral.

**Refer to chronic condition plan of care for health management interventions.**

**NURSING DIAGNOSIS: acute/chronic Pain****May Be Related To**

Physical agents (e.g., disease process; chronic physical disability)  
Emotional distress; fatigue

**Possibly Evidenced By**

Self-report of pain intensity/characteristics using standardized scale/instrument  
Facial expression of pain; restlessness, irritability  
Appetite change; anorexia; alteration in sleep pattern  
Positioning to ease pain  
Changes in vital signs (acute pain)

**Desired Outcomes/Evaluation Criteria—Client Will****Pain Control NOC**

Report pain is relieved or controlled, using self-report pain tool.  
Demonstrate reduction in pain-related behaviors if unable to provide self-report.  
Identify and use nonpharmacological methods that provide relief.  
Follow prescribed pharmacological regimen.

**Family/SO(s) Will**

Cooperate in pain management program.

**ACTIONS/INTERVENTIONS****RATIONALE****Pain Management: Acute/Chronic NIC****Independent**

Perform a comprehensive pain evaluation, including location, characteristics, onset, duration, frequency, quality, severity using 0 to 10, or similar coded scale, and precipitating or aggravating factors. Note cultural issues impacting reporting and expression of pain. Determine client's acceptable comfort-function level.

Provides baseline information from which a realistic plan can be developed, keeping in mind that verbal and behavioral cues may have little direct relationship to the degree of pain perceived. If self-report is not possible, behavior or physical responses may be helpful (Bjoro & Herr, 2008). Note: Often client does not feel the need to be completely pain-free but is able to be more functional when pain is at lower level on the pain scale.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Determine possible pathophysiological and psychological causes of pain, such as may be caused by inflammation, fractures, cancer process, surgery, grief, fear, anxiety, or delirium.	Pain is associated with many factors that may be interactive and increase the degree of pain experienced and affect choice of interventions.
Assess client's perception of pain, being aware of client's cognitive status along with behavioral and psychological responses. Determine client's attitude toward, and use of, pain medications and locus of control—internal or external.	Helps identify client's needs, ability to adequately express self, and pain control methods found to be helpful or not helpful in the past. Note: Individuals with external locus of control may take little or no responsibility for pain management.
Encourage client and family to express feelings and concerns about opioid use.	Inaccurate information regarding drug use, fear of addiction, or oversedation could impair pain management efforts.
Verify current and past analgesic and drug use, including alcohol.	May provide insight into what has or has not worked in the past or may impact therapy plan.
Assess degree of personal adjustment to diagnosis, such as anger, irritability, withdrawal, and acceptance.	These factors are variable and often affect the perception of pain, ability to cope, and pain management success.
Discuss with SO(s) ways in which they can assist client and reduce precipitating factors.	Promotes involvement in care and belief that there are things they can do to help.
Instruct client in specific signs and symptoms and changes in pain intensity/characteristics requiring notification of primary care provider.	Unrelieved pain may be associated with progression of disease process or with complications that require medical management.
Involve caregivers in identifying effective comfort measures for client, such as use of nonacidic fluids, oral swabs, lip salve, and suctioning; skin and perineal care; and use of laxatives. Instruct in use of any needed equipment, such as suction and oxygen.	Managing troubling symptoms, such as nausea, dry mouth, dyspnea, and constipation, can reduce client's suffering and family anxiety, thus improving quality of life and allowing client and family to focus on other issues.
Demonstrate and encourage use of relaxation techniques, such as guided imagery, music, and meditation.	Can supplement analgesic therapy, especially during periods when client desires to minimize sedative effects of medication.
Monitor for, and discuss possibility of, changes in mental status, such as agitation, confusion, and restlessness.	Although causes of deterioration are numerous in terminal stages, early recognition and management of the psychological component are integral parts of pain management.
<b>Collaborative</b>	
Establish pain management plan with client, family, and healthcare providers, with options for management of breakthrough pain and including holistic options such as aromatherapy or Therapeutic Touch in plan as appropriate.	Inadequate pain management remains one of the most significant deficiencies in the care of the dying client. A stepwise plan or analgesic ladder developed in advance increases client's level of trust that comfort will be maintained, reducing anxiety.
Schedule and administer analgesics, as indicated, to maximal dosage. Use various modalities such as patch, lollipop, sublingual, or combinations of medications, as indicated.	Helps maintain "acceptable" level of pain. Various drugs, dosages, and combinations allow for smaller doses and fewer side effects.
Plan for aggressive pain management, as indicated. Notify physician if regimen is inadequate to meet pain control goal.	Primary goal is for client to be comfortable. Sometimes frequent alterations are required in achieving this, but medications and comfort measures must be sufficient to ensure that client is not suffering.
Instruct client, family, and caregiver in use of sustained-release formulations, around-the-clock dosing, and breakthrough pain management and technology, such as pump or patient-controlled analgesia (PCA) for pain control.	By understanding and managing these factors, pain relief can be enhanced and quality of life improved.
Review medicinal options to treat constipation.	Various "cocktails" are available to manage constipation associated with use of opioid pain medications, reduced peristalsis, and lack of food intake. This is a frequent problem that must be managed to reduce client discomfort.

Refer to CP: Cancer; ND: acute/chronic Pain for additional interventions.

## NURSING DIAGNOSIS: Fatigue

### May Be Related To

Illness; anemia; malnutrition  
Stressors; anxiety; depression; exposure to negative life event

### Possibly Evidenced By

Tiredness; nonrestorative sleep pattern  
Insufficient energy; lethargy; drowsiness; increase in rest requirement  
Decreased performance; impaired ability to maintain usual routines  
Disinterest in surroundings; introspection

### Desired Outcomes/Evaluation Criteria—Client Will

#### Energy Conservation NOC

Identify negative factors affecting performance and eliminate or reduce their effects when possible.  
Adapt lifestyle to energy level.  
Verbalize understanding of potential loss of ability in relation to existing condition.

#### Fatigue Level NOC

Maintain or achieve slight increase in activity tolerance evidenced by manageable level of fatigue or weakness.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Energy Management NIC</b> <i>Independent</i> Assess severity of fatigue on 0 to 10 or similar coded scale.	The fatigue experienced by the terminally ill can arise from both physical and psychological causes. This fatigue has multiple components, including symptoms of tiredness, a general lack of energy not relieved by rest, diminished mental capacity, and subjective weakness associated with difficulty in performing activities of daily living (Portenoy et al, 1999; Grgis et al, 2006).
Assess sleep pattern and note changes in thought processes and behaviors.	Multiple factors can aggravate fatigue, including sleep deprivation, emotional distress, cognitive impairment (may be related to effects or side effects of medications/therapies, or progression of disease process).
Recommend scheduling activities for periods when client has most energy. Adjust activities as necessary, reducing intensity level or discontinuing activities, as indicated.	Prevents overexertion and allows for some activity within client's ability.
Encourage client to do whatever possible, for example, self-care, sit in chair, or visit with family and friends. Plan for shorter activities.	Provides for sense of control and feeling of accomplishment.
Instruct client, family, and caregiver in energy conservation techniques. Emphasize necessity of allowing for frequent rest periods following activities.	Enhances performance while conserving limited energy and preventing increase in level of fatigue.
Plan family and friend visits around client's increased sleep time and shorter periods of alertness.	Client may become tired easily and will sleep more. In addition, client may have periods of unresponsiveness or confusion or seem to be in a dream state. This may be distressing to families/visitors.
Demonstrate proper performance of/assist with activities of daily living (ADLs), ambulation, and position changes. Emphasize safety measures such as use of assistive devices, temperature of bath water, and keeping pathways clear of furniture.	Protects client and caregiver from injury during activities.
Encourage nutritional intake and use of supplements, as appropriate.	Client may or may not want to eat, but food can be offered, if client is able to eat. Easy-to-digest foods that client enjoys may help meet energy needs for activity.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Discuss future plans regarding food and fluid, as indicated. Help client's family understand that forced eating and drinking may harm instead of help.	As the body starts the natural process of dying, the need for food and fluids decreases due to the shutdown of body systems. At this point, dehydration associated with the dying process actually causes analgesic effects (Allen, 2008). Intravenous (IV) fluids and enteral feedings do not prolong life of the dying person. In fact, they may increase discomfort and hasten death. For example, IV fluids can cause edema, increased pain from inflammation, and fluid overload, whereas enteral feedings can cause pulmonary congestion and pneumonia (Suter et al, 2008).
Document cardiopulmonary response to activity—weakness, fatigue, dyspnea, arrhythmias, and diaphoresis.	Can provide guidelines for participation in activities and changes in the plan of care and level of assistance required.
Monitor breath sounds. Note feelings of panic or air hunger.	Hypoxemia increases sense of fatigue and impairs ability to function.
<b>Collaborative</b> Collaborate in identifying causes of fatigue that can be treated (e.g., medication effects, electrolyte levels, anemia, pain, depression).	If an etiology for fatigue can be determined, the condition should be treated appropriately.
Provide supplemental oxygen as indicated and monitor response.	Increases oxygenation, may decrease work of breathing, reducing anxious feelings. Evaluates effectiveness of therapy.

## NURSING DIAGNOSIS: Grieving/Death Anxiety

### May Be Related To

Anticipation of pain, suffering; anticipatory loss of body processes  
 Anticipation of impact of death on others  
 Confronting the reality of terminal disease; perceived imminence of death  
 Uncertainty about the existence of/encountering a higher power

### Possibly Evidenced By

Fear of pain/suffering related to dying  
 Negative thoughts related to death and dying  
 Worried about the impact of one's own death on significant other  
 Anger; despair; blaming; psychological distress

### Desired Outcomes/Evaluation Criteria—Client Will

#### Grief Resolution NOC

Verbalize understanding of the dying process.  
 Discuss spiritual concerns or unresolved conflicts.

#### Dignified Life Closure NOC

Identify and express feelings appropriately.  
 Participate in decisions regarding basic care and dying process.  
 Verbalize sense of control over remaining time.

### Family Will

#### Grief Resolution NOC

Ventilate conflicts and feelings related to illness and death.  
 Verbalize understanding of, and progress through, the stages of grief and loss.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Grief Work Facilitation NIC</b> <i>Independent</i> Facilitate development of a trusting relationship with client and family.	Trust is necessary before client and family can feel free to open personal lines of communication with the care team and address sensitive issues.

(continues on page 976)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Assess client and SO for stage of grief currently being experienced. Explain process, as appropriate.	Knowledge about the grieving process reinforces the normalcy of feelings and reactions being experienced and can help client deal more effectively with them.
Provide open, nonjudgmental environment. Use therapeutic communication skills of active-listening clarifying statements, inviting questions, and acknowledgment.	Promotes and encourages realistic dialogue about feelings and concerns. Empowers effective communication.
Encourage verbalization of thoughts and concerns. Accept expressions of sadness, anger, and rejection. Acknowledge normalcy of these feelings.	Client may feel supported in expression of feelings by the understanding that deep and often conflicting emotions are normal and experienced by others in this difficult situation (Otis-Green, 2008b).
Be aware of mood swings, hostility, and other acting-out behavior. Set limits on inappropriate behavior and redirect negative thinking.	Indicators of ineffective coping and need for additional interventions. Preventing destructive actions enables client to maintain control and sense of self-esteem.
Monitor for signs of debilitating depression such as statements of hopelessness, desire to "end it now." Ask client direct questions about state of mind.	Client may be especially vulnerable when recently diagnosed with end-stage disease process and/or when discharged from hospital. Fear of loss of control or concerns about managing pain effectively may cause client to consider suicide.
Reinforce teaching regarding disease process and provide information as requested and appropriate about dying. Be honest; do not give false hope while providing emotional support.	Client and SO benefit from factual information. Individuals may ask direct questions about death, and honest answers promote trust and provide reassurance that correct information will be given.
Review past life experiences, role changes, sexuality concerns, and coping skills. Promote an environment conducive to talking about things that interest client.	This is an opportunity to identify skills that may help individuals cope with grief of current situation more effectively. Note: Issues of sexuality remain important at this stage, such as feelings of masculinity or femininity, giving up caretaker or provider role within family, and ability to maintain sexual activity or closeness, if desired.
Investigate evidence of conflict, expressions of anger, and statements of despair, guilt, hopelessness, and inability to grieve.	Interpersonal conflicts and angry behavior may be client's and SO's way of expressing or dealing with feelings of despair or spiritual distress, necessitating further evaluation and support.
Determine way that client and SO understand and respond to death—cultural expectations, learned behaviors, experience with death of close family members or friends, and beliefs about life after death, spirituality, or faith in a higher power.	These factors affect how each individual faces death and influences how he or she may respond and interact.
Assist client and SO to identify strengths in self or situation and support systems.	Recognizing these resources provides opportunity to work through feelings of grief.
Be aware of own feelings about death. Accept whatever methods client and SO have chosen to help each other through the process.	Caregiver's anxiety and unwillingness to accept reality of possibility of own death may block ability to be helpful to client and SO, necessitating enlisting the aid of others to provide needed support.
<b>Dying Care NIC</b> Provide open environment for discussion with client and SO, when appropriate, about desires and plans pertaining to death, including making a will, burial arrangements, tissue donation, death benefits, insurance, time for family gatherings, and how to spend remaining time.	If client and SO are mutually aware of impending death, they may more easily deal with unfinished business or desired activities. Having a part in problem-solving and planning can provide a sense of control over anticipated events.
Encourage participation in care decisions.	Allows client to retain some control over life.
Visit regularly and provide physical contact as appropriate and desired, or provide frequent phone support as appropriate for setting. Arrange for care provider or support person to stay with client, as needed.	Helps reduce feelings of isolation and abandonment. Provides respite and time for SO and family to meet own needs and complete required activities.
Allow SO to be physically close, giving permission, instruction, and opportunities to touch the client.	Family and SO may need encouragement to touch the client, which is therapeutic to both the patient and the SO.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Provide time for acceptance, final farewell, and arrangements for memorial or funeral service according to individual spiritual, cultural, and ethnic needs.	Accommodation of personal and family wishes helps reduce anxiety and may promote sense of peace.
<b>Collaborative</b> Determine spiritual needs and/or conflicts and refer to appropriate team members, including clergy or spiritual advisor and parish nurse.	Providing for spiritual needs, forgiveness, prayer, devotional materials, or sacraments as requested can relieve spiritual pain and provide a sense of peace. (Refer to ND: risk for Spiritual Distress.)
Refer to appropriate counselor, as needed, such as psychiatric clinical nurse specialist, social worker, psychologist, and pastoral support.	Compassion and support can help alleviate distress or palliate feelings of grief to facilitate coping and foster growth.
Refer to visiting nurse or home-health agency if hospice services not available.	Provides support in meeting physical and emotional needs of client and SO and can supplement the care family and friends are able to give.
Identify need for and appropriate timing of antidepressants or antianxiety medications.	May alleviate distress and enhance coping, especially for clients not requiring analgesics.

### NURSING DIAGNOSIS: compromised family Coping

#### May Be Related To

Exhaustion of supportive person's capacity  
Insufficient understanding of information by a support person  
Family disorganization; insufficient reciprocal support

#### Possibly Evidenced By

Assistive behaviors by support person produce unsatisfactory results  
Client concern about support person's response to health problem  
Limitation in communication between support person and client; support person withdraws from client  
Protective behavior by support person incongruent with client's abilities/need for autonomy

#### Desired Outcomes/Evaluation Criteria—Family Will

#### Family Coping NOC

Express feelings freely among family members.  
Use available support system/community resources.  
Engage in decision making for resolution of identified problems.  
Share responsibility for family duties and care tasks as appropriate.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Family Involvement Promotion NIC</b> <i>Independent</i> Assess level of anxiety present in family and SO.	Anxiety level needs to be dealt with before problem-solving can begin. Individuals may be so preoccupied with own reactions to situation that they are unable to respond to another's needs.
Establish rapport and acknowledge difficulty of the situation for the family.	Listening intently helps SO/family feel they have been heard. May assist SO to accept what is happening and be willing to share problems with healthcare providers.
Determine level of coping impairment. Evaluate current behaviors that may be interfering with the care of client.	Information about family problems such as divorce or separation, alcoholism, other drug use, or abusive situation will be helpful in determining options and developing an appropriate plan of care.
Note client's emotional and behavioral responses resulting from increasing weakness and dependency, such as depression, withdrawal, hostility, hallucinations, and delusions.	Approaching death is most stressful when client and family coping responses are strained, resulting in increased frustration, guilt, and anguish.

(continues on page 978)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Discuss underlying reasons for client behaviors with family.	When family members know why client is behaving differently, it may help them understand, accept, and deal with unusual behaviors.
Assist family and client to understand “who owns the problem” and who is responsible for resolution. Avoid placing blame or guilt.	When these boundaries are defined, each individual can begin to take care of own self and stop taking care of others in inappropriate ways.
Determine current knowledge and perceptions of the situation.	Provides information on which to begin planning care and making informed decisions. Lack of information or unrealistic perceptions can interfere with individual's responses to illness situation.
Assess current actions of SO and how they are received by client.	SO may be trying to be helpful, but actions are not perceived as such by client. SO may be withdrawn or too protective.
Facilitate family conference; include all family members, as appropriate. Provide and reinforce information about terminal illness, death, and future family needs. Involve SO/family with client in planning care.	Knowledge can help the family prepare for eventualities and deal with the actual death process. Increases understanding of necessary activities and steps to be taken to deal with funeral preparations, legal and financial concerns, and survivor issues.

#### *Collaborative*

Refer to appropriate resources for assistance, as indicated, including family counseling, psychotherapy, community support groups, and respite care.

May need additional assistance in resolving family issues, making peace, and maintaining personal well-being.

## NURSING DIAGNOSIS: risk for Spiritual Distress

### Possibly Evidenced By

Anxiety; stressors; depression  
Separation from support systems  
Barrier to experiencing love; low self-esteem; inability to forgive

### Desired Outcomes/Evaluation Criteria—Client Will

### Spiritual Health NOC

Identify meaning and purpose in own life.  
Report sense of connectedness with self/others.  
Verbalize feelings of peacefulness or spiritual contentment.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Spiritual Support NIC</b>	
<i>Independent</i>	
Listen to client's and SO's reports and expressions of anger or concern.	May reveal many conflicting thoughts and beliefs, for example, that illness or situation is a punishment for wrongdoing or that death is desirable or feared. Dying client faces momentous losses of physical control and function, of independence, of relationships, of possibilities, and ultimately of life itself. To family members and friends, the loss of a loved one causes great stress and temporarily impairs concentration, decision making, and work performance.
Determine client's religious or spiritual orientation, current involvement, and presence of conflicts in current circumstances.	Provides insight as to where client currently is and what hopes for the future may be. Note: Individuals reporting high spirituality were less hopeless, had less desire to hasten their deaths, and had less suicidal ideation.
Assess sense of self-concept, worth, and ability to enter into or maintain loving relationships.	Necessary to provide firm foundation for growth and guiding client and family through life closure and completion tasks.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Explore interpretation and relationship of spirituality, concept of life, and death and illness to client's spiritual centeredness.	Identifying the meaning of these issues may be helpful in forming or stating a belief system that enables client to move forward. Comfort can be gained when family and friends share client's beliefs and support search for spiritual knowledge.
Explore ways that spirituality or religious practices, such as music, prayer, meditation, and rituals, have affected client's life.	Allows client to explore spiritual needs and decide what fits own view and provides support for dealing with current situation.
Determine support systems available to and used by client and SO.	May help identify strengths and weaknesses in relationship dynamics that the client and SOs may want to address, such as expressing love, forgiveness, and support.
Encourage client to be introspective in search for peace and harmony.	Finding peace within will carry over to relationships with others and one's outlook on life and death.
Establish environment that promotes free expression of feelings and concerns.	May help identify the real need of the day. For example, the dying person may not hope for cure or postponement of death but rather that on the next day, he or she will feel better with fewer physical and emotional discomforts.
Have client and SO identify and prioritize current and immediate needs regarding faith, influence, and community.	Helps client and SO focus on what needs to be done and identify manageable steps to take.
Make time for nonjudgmental discussion of cultural and philosophical issues and questions about spiritual impact of illness and/or impending death.	Spiritual or religious practices, customs, and rituals often play important roles, especially at a time of such significant transition in life.
Discuss difference between grief and guilt and help client to identify and deal with each, assuming responsibility for own actions.	Identifies persons at risk for complicated grief and bereavement and its associated depression and complications. May provide opportunities for resolution.
Use therapeutic communication skills of gentle stillness, reflection, conveying respect through tone of voice and body language, and active-listening.	Encourages client and SO to identify and express end-of-life concerns, hopes, fears, and expectations openly and honestly in a caring milieu.
Review coping skills used and their effectiveness in current situation.	Helps client and SO remember and call upon strengths that have been helpful in other situations. May free the client to be "more" creative, loving, and into the experience of well-being.
Suggest use of storytelling, journaling, or taping thoughts.	Helps client explore and find own solutions to concerns. Identifies strengths to incorporate into plan and techniques needing revision.
Determine how involved in physical care the family members want to be. Establish with client and SO wishes for the moment of death.	Clarification of specific wishes can be helpful in reducing stress and allow for needed differences in response.
<b>Collaborative</b>	
Encourage participation in desired religious activities, prayer, meditation, or contact with minister, spiritual advisor, or grief counselor.	May prove beneficial to both client and family members in reflecting on life and death issues. Can assist in clarifying values and ideas, recognizing and resolving feelings, and promoting comfort. Validating one's beliefs in an external way can support and strengthen the inner self.

Refer to CP: Psychosocial Aspects of Care; ND: risk for impaired Religiosity for additional interventions.

NURSING DIAGNOSIS: <b>risk for caregiver Role Strain</b>
<b>Possibly Evidenced By</b>
Complexity of caregiving activities; extended duration of caregiving required Ineffective coping strategies; ineffective family adaptation Partner is caregiver; insufficient respite for caregiver
(continues on page 980)

**NURSING DIAGNOSIS:** **risk for caregiver Role Strain** (continued)**Desired Outcomes/Evaluation Criteria—Caregiver Will****Caregiver Role Endurance NOC**

Demonstrate mastery of direct/indirect care tasks.  
Share responsibility for caregiving tasks with family members/support system.  
Engage in appropriate leisure activities/respite.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Caregiver Support NIC</b>	
<i>Independent</i>	
Determine caregiver's health, level of commitment, responsibility, and involvement in care. Use assessment tool, such as Burden Interview, to further clarify caregiver's abilities, when appropriate.	Terminal care taxes caregiver and may alter ability to meet client's and own needs (Otis-Green, 2008a).
Ascertain caregiver's understanding and acceptance of client's wishes and advance directives.	If caregiver is not in total agreement with client's wishes, role strain may be intensified as specific decisions are made regarding care and termination of therapies.
Involve SO in information giving, problem-solving, and care of client, as appropriate. Instruct in medication administration techniques, needed treatments, and appropriate complementary therapies, such as massage, herbs, aromatherapy, and relaxation techniques. Ascertain adeptness with required equipment.	Information can reduce feelings of helplessness and uselessness. Helping a client and family find comfort is often more important than adhering to strict routines. However, family caregivers need to feel confident with specific care activities and equipment. Note: Use of complementary medicine is increasing for pain and symptom relief with lessened side effects.
Provide positive feedback for efforts.	Helps caregiver recognize and feel valued for contribution to care.
Emphasize importance of self-nurturing, personal needs, and social contacts.	Taking time for self can help lessen risk of being overwhelmed by situation.
Identify and schedule alternative care resources, such as family, friends, sitter, and respite services, as needed.	As client's condition worsens, primary caregiver will require additional help from other sources to maintain client at home as desired while still meeting own needs for rest and personal time.
<i>Collaborative</i>	
Refer to community resources to address specific needs, as indicated, such as insurance/financial services and hospice/respite care.	May need additional assistance to facilitate client's wishes for end-of-life care and to support caregiver's well-being.
Arrange for appropriate prescriptions for SO (e.g., sedative, hypnotic).	Mild medication may be beneficial in reducing anxiety and promoting sleep, which, in turn, can enhance coping ability.

## DISASTER CONSIDERATIONS

**I. Problem**

- a. The bigger the disaster or catastrophe, the greater the number of people involved and the wider the effect.
- b. Physical effects of a catastrophic event can vary depending on the type of disaster.
  - i. Explosive devices, transportation accidents, hurricanes, earthquakes, tornados, or floods—burns, traumatic brain and crush injuries, amputations
  - ii. Release of chemical agents—burns, pulmonary or other organ damage, neurological impairment
  - iii. Biological weapons or infections/disease outbreaks (e.g., avian flu or pandemic influenza)
  - iv. Radioactive contamination or exposure—burns, radiation sickness, cancer (long-term concern)

**c. Disaster classifications and examples:**

- i. Time limited—tornado
- ii. Evolving—wildfires, floods, hurricanes
- iii. Prolonged—drought
- iv. Recurrent—wildfire followed by spring flood

**II. Consequences**

- a. Following any disaster, those involved—victims, rescuers, and the surrounding community—suffer from a variety of responses.
- a. Disaster or extreme events can have indirect health-related effects.
  - i. Exacerbation of chronic condition, such as heart or respiratory problems.

## G L O S S A R Y

- ii. Precipitation of emergent conditions such as premature births, seizures, or mental health conditions.
- c. Psychological ramifications
  - i. Immediate stressors may cause anxiety or panic disorders.

- ii. The playing and replaying of the events in one's mind may lead to suicidal thoughts and posttraumatic stress disorder (PTSD).
- iii. Repeated media coverage can magnify the effects; people far removed from the scene may also suffer.

**Acute stress disorder (ASD):** Development of specific fear behaviors that last from 3 days to 1 month after exposure to traumatic event. May progress to PTSD if symptoms persist beyond 1 month.

**Acute stress reaction (ASR):** Refers to a range of transient conditions that develop in response to a traumatic event. Onset of some signs and symptoms may occur within minutes of the event and in most cases will disappear within days or even hours.

**Biological agents:** Viruses (smallpox), bacteria (anthrax, *Salmonella*), other agents including toxins (botulism) that can cause illness or death.

**Chemical agents:** Poisonous gases, liquids, or solids, including nerve agents (sarin), biotoxins (ricin), choking or pulmonary agents (chlorine, ammonia), blood agents (cyanide), caustics (hydrofluoric acid), vesicants or blister agents (lewisite, mustard gas), or long-acting anticoagulants (super warfarin) that can cause serious injury or death.

**Disaster:** Generally refers to a catastrophic natural or manmade event affecting a large population resulting in injury, death, and destruction of property that overwhelms local resources.

**Eye movement desensitization and reprocessing (EMDR):**

Information-processing psychotherapy technique integrating elements of psychodynamic, cognitive-behavioral, interpersonal, experiential, and body-centered therapies to assist individuals to deal with anxious feelings and stress associated with traumatic memories (EMDR Institute, n.d.).

**Posttraumatic stress disorder (PTSD):** Intense physical and psychological distress that ensues following a traumatic event, manifested by horrifying memories, reexperiencing the event or flashbacks, recurring fears, and feelings of helplessness. May be acute—beginning within 6 months and not lasting longer than 6 months; chronic—lasting longer than 6 months; or delayed—period of latency of 6 months or more.

**Psychological first aid:** An evidence-based set of skills to help children, adolescents, adults, and families immediately following a disaster event to reduce the associated distress and to foster short- and long-term adaptive coping by providing information, support, comfort, and safety. It is the behavioral health correlation to physical first aid with the goal being to “stop the bleeding” (Brymer et al, 2006).

## CARE SETTING

Wherever disaster occurs and includes triage areas, aid stations, clinics, hospital and emergency centers, and community shelters.

## RELATED CONCERNs

Burns: thermal, chemical, and electrical—acute and convalescent phases, page 740

Craniocerebral trauma—acute and rehabilitation phases, page 226

Fractures, page 702

Pediatric considerations, page 993

Pneumonia, page 147

Psychosocial aspects of care, page 835

Sepsis/septic shock, page 772

## CLIENT ASSESSMENT DATABASE

Data depend on specific injuries incurred and presence of chronic conditions (refer to specific plans of care for appropriate data, such as burns, multiple trauma, cardiac and respiratory conditions, etc.), psychological response to event, and timing of presentation for care.

### DIAGNOSTIC DIVISION MAY REPORT

#### ACTIVITY/REST

- Sleep disturbances—recurrent intrusive dreams of the event, nightmares, difficulty in falling or staying asleep; hypersomnia with intrusive thoughts, flashbacks
- Fatigue

### MAY EXHIBIT

- Listlessness

(continues on page 982)

**CLIENT ASSESSMENT DATABASE** (contd.)**MAY REPORT** (continued)**MAY EXHIBIT** (continued)**CIRCULATION**

- Palpitations
- Hot flashes or chills

- Tachycardia
- Sweating
- Cold, clammy hands
- Elevated blood pressure (BP) (anxiety)
- Decreased BP (dehydration, hypovolemia)

**EGO INTEGRITY**

- Excessive worry about event
- Avoidance of circumstances or locations associated with incident
- Sense of inner turmoil
- Dry mouth, upset stomach, lump in throat
- Perceived threat to physical integrity or self-concept
- Questioning of God's purpose, abandonment

- Facial expression in keeping with level of anxiety—furrowed brow, strained face, eyelid twitch
- Labile emotions
- Inappropriate humor
- • P May show fear of strangers, or scared to leave parent(s)
- • P Fussy, irritable, aggressive, extreme temper-tantrums; impulsiveness and aggressive behavior more likely in adolescents (Hamblen & Barnett, 2016)
- • P Regression in habits (e.g., sucking thumb)

**ELIMINATION**

- Frequent urination
- Diarrhea

- • P Peds Regression in learned skills (e.g., toileting)

**FOOD/FLUID**

- Lack of interest in food, dysfunctional eating pattern—decreased or increased intake
- Nausea, vomiting, gastric distress

**NEUROSENSORY**

- Lightheadedness, dizziness
- Anticipation of misfortune to self or others
- Feeling stuck
- Absence of other mental disorder

- Confusion, memory loss
- Motor tension, shakiness, jitteriness, trembling, easily startled
- Apprehensive expectation, rumination
- Excessive vigilance, hyperattentiveness
- • P Time skew (missequencing trauma-related events when recalling the memory)
- • P Omen formation (belief that there were warning signs predicting trauma and if child is alert enough they will avoid future traumas) (Hamblen, 2016)
- Distractibility, difficulty concentrating or making decisions, shortened attention span
- Irritability, impatience
- Psychic numbing

**PAIN/DISCOMFORT**

- Muscle aches, tension headaches, chest pain
- Pain related to physical injuries or comorbid conditions

- Guarding or distraction behaviors

**RESPIRATORY**

- Shortness of breath
- Smothering sensation

- Increased respiratory rate

**SAFETY**

- Increased smoking, substance use or abuse
- Fear of harm to self or others

**SEXUALITY**

- Decreased libido

**MAY REPORT (continued)****MAY EXHIBIT (continued)****SOCIAL INTERACTIONS**

- Concern for well-being of others
- Questioning own actions, survival
- Difficulty participating in social settings
- Reluctance to engage in usual activities, work

- Withdrawal

**TEACHING/LEARNING**

- ***Discharge plan considerations:*** Dependent on individual situation, level of support, and available resources

**DIAGNOSTIC STUDIES**

Dependent on injuring agent and exposure and availability of resources for testing and procedures.

**NURSING PRIORITIES**

1. Prevent or treat life-threatening conditions.
2. Prevent further injury and spread of infection.
3. Support efforts to cope with situation.
4. Facilitate integration of event.
5. Assist community in recovery process and preparing for future occurrences.

**DISCHARGE GOALS**

1. Free of preventable complications.
2. Anxiety reduced to a manageable level.
3. Beginning to cope effectively with situation.
4. Plan in place to meet needs after discharge.
5. Community preparedness enhanced.

**NURSING DIAGNOSIS: risk for Injury/physical Trauma****Possibly Evidenced By**

Unsafe environment

Exposure to toxic chemical (chemical pollutants, poisonous agents), corrosive product, radiation; contamination of food or water

Immunization level within community; exposure to pathogen

**Desired Outcomes/Evaluation Criteria—Client/Caregivers Will****Physical Injury Severity |NOC**

Minimize degree of and prevent further injury.

**Personal Safety Behavior |NOC**

Verbalize understanding of condition and specific needs.

Identify interventions appropriate to situation.

Demonstrate behaviors necessary to protect self from further injury.

Accept responsibility for own care and follow up as individually able.

**ACTIONS/INTERVENTIONS****RATIONALE****Triage: Disaster |NIC****Independent**

Acquire information about nature of emergency, accident, or disaster.

Identifies basic resource needs and helps to prepare staff for appropriate level of response based on customary injuries and healthcare needs usually associated with specific event.

Prepare area and equipment; check and restock supplies.

Assists in providing safe medical and nursing care in anticipation of emergency need.

(continues on page 984)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Assist in prioritizing (triaging) clients for treatment, including decontamination. Monitor for and treat life-threatening injuries.	Promotes efficient care of those who can be medically treated and maximizes use of resources. Note: In routine emergency situations, the goal is to do the best for each individual. However, in a disaster, the focus of treatment shifts to do the greatest good for the greatest number.
Determine primary needs and specific complaints of client. Check for medical alert tag.	Information necessary for triaging to appropriate services. <b>P</b> Note: Pediatric clients are better able to compensate during early hypovolemic shock than adults, creating a false impression of normalcy (American Academy of Pediatrics [AAP], 2006).
Obtain additional medical information, including preexisting conditions, allergies, and current medication. Perform more in-depth assessment as time allows and condition warrants.	Provides for assessment and treatment of conditions that might not be evident initially.
Determine client's developmental level, decision-making ability, level of cognition, and competence.	Affects treatment plan regarding issues of informed consent, self-care, client teaching, and discharge.
Evaluate individual's response to event, mood, coping abilities, and personal vulnerability.	People react to traumatic situations in many ways and may exhibit a wide range of responses—from no visible response to wild emotions. This may result in carelessness or increased risk taking without considerations of consequences or inability to act on own behalf, including protecting self.
Ascertain knowledge of needs and injury prevention and motivation to prevent further injury.	Indicator of need for information and assistance with making positive changes, promoting safety and sense of security.
Discuss importance of self-monitoring of conditions and emotions that can contribute to occurrence of injury—shock state, ignoring basic needs, fatigue, anger, and irritability.	Recognizing these factors and dealing with them appropriately, including seeking support and assistance, can reduce individual risks.
Note socioeconomic status and availability and use of resources.	May determine ability to access help for identified problems.
<b>Collaborative</b> Work with other agencies, such as law enforcement, fire department, Red Cross, and ambulance and EMTs, as indicated. Follow prearranged roles when participating in a community disaster plan.	During a disaster, many people are involved with care of victims. Most communities have disaster plans in which nurses will participate.
<b>Triage: Emergency Care NIC</b> Identify and manage life-threatening situations—airway problems, bleeding, and diminished consciousness.	Stabilization of medical condition is necessary before proceeding with additional therapies. <b>P</b> Note: Children are at greater risk than adults when exposed to chemical agents/poisonous gases because of (1) higher minute volume, (2) increased skin permeability, (3) greater body surface to weight ratio, (4) less intravascular volume increasing risk of hypovolemic shock, (5) shorter stature increasing exposure to greatest gas vapor density at ground level (Foltin et al, 2008).
Obtain and assist with diagnostic studies, as indicated.	Choice of studies is dependent on individual situation and availability of resources.
Provide therapeutic interventions as individually appropriate. (Refer to specific CPs; e.g., Burns, Fractures, Craniocerebral Trauma, Myocardial Infarction, Chronic Obstructive Pulmonary Disease, Respiratory Failure/Ventilatory Assistance.)	Specific needs of client and the level of care available at a particular site determine response.
Provide written instructions and list of resources for later review.	Client and significant other(s) (SO[s]) are generally not able to assimilate information at time of crisis and may need reinforcement or want additional information.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Identify community resources, including shelter, neighbors, friends, and government agencies available for assistance.	May need assistance or ongoing monitoring postdischarge to deal with self-care needs as well as safe housing and other life requirements. Note: Release of client without active support increases personal risk because of possibility of unrecognized or subacute injury or delayed psychological response.
Refer to other resources, as indicated, such as counseling and psychotherapy.	Immediate “debriefing” or counseling is beneficial for dealing with crisis to enhance ability to meet own needs.

### NURSING DIAGNOSIS: **risk for Infection**

#### Possibly Evidenced By

Exposure to disease outbreak; inadequate vaccination  
Alteration in skin integrity; invasive procedures  
Chronic illness, malnutrition

#### Desired Outcomes/Evaluation Criteria—Client Will

##### Risk Control NOC

Verbalize understanding of individual exposure and risk factor(s).  
Identify interventions to prevent and reduce risk of infection.

##### Infection Severity NOC

Be free of or demonstrate resolution of infection.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Infection Control NIC</b>	
<b>Independent</b>	
Note risk factors for occurrence of infection—environmental exposure (including other individuals sharing close quarters such as shelter residents), compromised host, traumatic injury, loss of skin integrity. Determine client’s proximity to incident. Be aware of incubation period for various diseases/likely exposure. (Refer to local public health department or the cdc.gov website for information specific to exposure.)	Understanding nature and properties of infectious agents and individual’s exposure determines choice of therapeutic intervention. Note: Those upwind of an aerosol release of a biological agent may have little or no exposure to the agent.
Observe for signs and symptoms of infective agent and systemic infection—fever, chills, diaphoresis, altered level of consciousness (LOC), and positive blood cultures. Investigate presence of rash.	Initial symptoms of some agents include fever, fatigue, joint aches, and headache similar to influenza. The infection may even be misdiagnosed as an influenza-like infection (ILI), unless healthcare providers maintain an index of suspicion and obtain additional diagnostic studies. <b>P</b> Note: The immature immunological system of children places them at higher risk for developing infections (AAP, 2006).
Practice and demonstrate proper hand hygiene.	First-line defense to limit spread of infections.
Provide for infection precautions or isolation, as indicated—standard precautions of gown, gloves, face shield or goggles, respiratory mask or filter, and reverse or negative pressure room, when available.	Reduces risk of cross-contamination to staff, visitors, and other clients.
Group or cohort individuals in facility/shelter with same diagnosis or exposure as resources require.	Limited resources may dictate open ward-like environment but need to control spread of infection still exists.
Monitor visitors/shelter residents, caregivers, and volunteers for infectious diseases.	Prevents exposure of client to further infection and may reveal additional cases.
Review individual nutritional needs, appropriate exercise program, and need for rest.	Essential for well-being and recovery.

(continues on page 986)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Instruct client/SO(s) in techniques to prevent spread of infection (e.g., hand hygiene, covering coughs, management of secretions), protect the integrity of skin, and care for wounds or lesions.	Self-care activities that may provide protection for client and others.
Emphasize necessity of taking antibiotics as directed, especially dosage and length of therapy.	Premature discontinuation of treatment when client begins to feel well may result in return of infection. However, unnecessary use of antibiotics may result in development of secondary infections or resistant organisms.
Monitor cleanliness of environment/shelter, food storage and preparation. <b>P</b> Provide for safe infant feeding/care. Designate quiet places to breastfeed, provide ready-to-use formula that requires no special mixing in disposable bottles that don't require cleaning if not breastfeeding (DeYoung, 2017).	Proper food-handling/feeding techniques and disposal of waste/diapers and incontinent pads/briefs as well as medical waste such as dressings reduce risk of spread of infection.
Involve community/shelter residents in education programs geared to increasing awareness of spread and prevention of communicable diseases.	Helps to reduce incidence of disease in the community as well as manage the dissemination of information.
<b>Collaborative</b>	
Obtain appropriate specimens for observation and culture and sensitivities testing—nose and throat swabs, sputum, blood, urine, or feces.	Provides information to diagnose infection and determine appropriate therapeutic interventions.
Assist with medical procedures, such as incision and drainage of abscess, bronchoscopy, or wound care, as indicated.	Helps determine causative factors for appropriate treatment and facilitates recovery.
Administer and monitor medication regimen (e.g., antimicrobials, topical antibiotics) and note client's response.	Determines effectiveness of therapy and presence of side effects.
Provide passive protection such as immune globulin, active protection (e.g., vaccination), or chemoprophylaxis, as appropriate.	May prevent development of infection following exposure or reduce the likelihood of acquiring disease in the future.
Alert proper authorities to presence of specific infectious agent and number of cases.	Diseases that could be caused by biological releases or that spread rapidly through populations have reporting requirements to local, state, and national agencies, such as the state health department or the Centers for Disease Control and Prevention (CDC). These agencies, in turn, have responsibilities for the public safety and welfare.

## NURSING DIAGNOSIS: [severe/panic] Anxiety

### May Be Related To

Threat to current status; threat of death  
Interpersonal contagion/transmission (e.g., of concerns or fears)  
Unmet needs; value conflict  
Situational crisis; exposure to toxins

### Possibly Evidenced By

Distress, apprehensiveness, irritability, worried about change in life event, self-focused, fear  
Scanning behavior, hypervigilance, restlessness  
Cardiovascular excitation; changes in vital signs  
Alteration in attention/concentration; rumination

### Desired Outcomes/Evaluation Criteria—Client Will

#### Anxiety Self-Control NOC

Acknowledge and discuss feelings.  
Verbalize accurate knowledge of current situation and potential outcomes.  
Identify healthy ways to successfully deal with stress.  
Report anxiety is reduced to a manageable level.  
Demonstrate problem-solving skills appropriate for individual situation.  
Use resources and support systems effectively.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Crisis Intervention NIC</b> <i>Independent</i> Perform screening/needs assessment for all individuals following event.	Initial reactions following event are varied, complex, and can be unstable. Acute stress reaction (ASR) is a transient condition developing within minutes or hours and although usually resolving within 2 to 3 days, early intervention (such as psychological first aid) may reduce progression to a more serious stress disorder (Department of Veterans Affairs and Department of Defense [VA/DoD], 2010).
Determine degree of anxiety or fear present; associated behaviors, such as laughter, crying, calm or agitation, excited or hysterical behavior; expressions of disbelief and/or self-blame; and reality of perceived threat.	Clearly understanding client's perception is pivotal to providing appropriate assistance in dealing with anxiety. Individual may be agitated or totally overwhelmed. Severe anxiety increases risk for client's own safety as well as the safety of others in the environment. <b>P</b> Note: Children are affected by their own reaction to the event as well as the transmission of anxiety or fear being experienced by parents and care providers, thus magnifying the psychological impact on the child (AAP, 2006).
Note cultural factors that may influence anxiety and response to event.	Individual responses are influenced by cultural values and beliefs and culturally learned patterns of one's family of origin impacting how the individual expresses emotions and attitudes toward assistance from others/government agencies or counseling services (Brymer et al, 2006). Note: Cultural or religious affiliations may impact responses of others client comes in contact with.
Note degree of disorganization.	Client may be unable to handle activities of daily living (ADLs) or work requirements and may need more intensive evaluation and intervention. <b>P</b> Children may regress—girls may express anxiety and sadness, whereas boys are more likely to display behavioral problems (AAP, 2006).
Maintain and respect client's personal space boundaries—approximately 4-foot circle around client.	Entering client's personal space without permission or invitation could result in an overwhelming anxiety response and, possibly, an overt act of violence. Respecting personal space helps client to feel safe, which is an important factor in client regaining or maintaining pre-event status (VA/DoD, 2010).
Create quiet area as able. Maintain a calm, confident manner. Speak in even tone using short, simple sentences. <b>P</b> Encourage parents to provide a calming presence, reassure child they are safe and share feelings as a family (Moreno, 2017).	Decreases sense of confusion, overstimulation, and enhances sense of safety. Helps client focus on what is said and reduces transmission of anxiety.
Develop trusting relationship with client.	Trust is the basis of a therapeutic nurse-client relationship and enables them to work together effectively.
Identify whether incident has reactivated preexisting or coexisting situations—physical or psychological.	Concerns or psychological issues will be recycled every time trauma is reexperienced and affect how the client views the current situation.
Determine presence of physical symptoms, such as numbness, headache, chest tightness, nausea, and pounding heart.	Physical problems need to be differentiated from anxiety symptoms so that appropriate treatment can be given.
Identify psychological responses—anger, shock, acute anxiety, panic, confusion, and denial. Record emotional changes.	Although these are normal responses at the time of the trauma, they will recycle again and again until they are dealt with adequately.
Discuss with client perception of what is causing anxiety or panic.	Increases ability to connect symptoms to subjective feeling of anxiety, providing opportunity to gain insight and control, and make desired changes.

(continues on page 988)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Assist client to correct any distortions being experienced.	Provides opportunity to clarify misperceptions, including possibility of survivor's guilt. Perceptions based on reality will help to decrease fearfulness.
<p><b>P</b> Use developmentally appropriate language to discuss event and its meaning to child. Have parents ask child what they already know, solicit questions, and answer honestly, focusing on basics and avoiding speculation (Moreno, 2017).</p>	Younger children usually have less understanding of abstract concepts and benefit from direct and simple language. Approaching adolescents "adult-to-adult" reinforces that you respect their feelings and concerns (Brymer et al, 2006).
Explore with client and SO the manner in which the client has coped with anxiety-producing events before the trauma.	May help client regain sense of control and recognize significance of trauma.
Engage client in learning new coping behaviors, such as progressive muscle relaxation and thought stopping.	Replacing maladaptive behaviors can enhance ability to manage and deal with stress. Interrupting obsessive thinking allows client to use energy to address underlying anxiety, while continued rumination about the incident can actually retard recovery. <b>P</b> One influence on child's well-being after disaster is how well parents hold themselves together. Note: Phenomenon of intergenerational transmission of trauma has been documented (Patterson, 2006).
Demonstrate and encourage use of techniques to reduce or manage stress and vent emotions such as anger and hostility.	Reduces likelihood of eruptions that can result in abusive behavior.
Give positive feedback when client demonstrates better ways to manage anxiety and is able to calmly and/or realistically appraise own situation.	Provides acknowledgment and reinforcement, encouraging use of new coping strategies. Enhances ability to deal with fearful feelings and gain control over situation, promoting future successes.
Engage client in simple tasks and advance responsibilities as appropriate.	Encourages individual to focus attention other than on self, enhancing sense of control and self-worth.
<b>Collaborative</b> Administer medications, as indicated, for example: Antianxiety agents, such as diazepam (Valium), buspirone (BuSpar), alprazolam (Xanax), and oxazepam (Serax)	Provides temporary relief of anxiety symptoms, enhancing client's ability to cope with situation. Also useful for alleviating feelings of panic and intrusive nightmares.
Antidepressants, such as fluoxetine (Prozac), paroxetine (Paxil), and bupropion (Wellbutrin)	Used to decrease anxiety, lift mood, aid in management of behavior, and ensure rest until client regains control of own self. Helpful in suppressing intrusive thoughts and explosive anger.
Refer for additional therapies, such as hypnosis, EMDR, or thought reprocessing therapy, as appropriate.	When used by trained therapist, these short-term therapies are particularly effective with individuals who have been traumatized or who have problems with anxiety and depression. Systematic desensitization, reframing, and reinterpretation of memories may be achieved through hypnosis.
Coordinate release or discharge to family, friend, or emergency services, as indicated.	Triaging and maximum use of resources may limit time allotted for care, and client may not be ready to meet own needs or assume full responsibility for self.
Educate survivors and public about risks and steps being taken to deal with problem. Include other members of healthcare team, stressing risks to themselves. Refer to such resources as the CDC or specific websites.	Nurses have a role in community education because they are close to the individuals affected. Providing accurate information and credible resources helps limit level of concern and transmission of anxiety. Current, timely information regarding biological concerns and healthcare needs can be accessed through such websites as www.cdc.gov, www.hhs.gov, and www.fbi.gov.

**NURSING DIAGNOSIS:** risk for Spiritual Distress**Possibly Evidenced By**

Exposure to natural disaster; environmental/life change  
Anxiety; stressors; depression  
Separation from support system; loss

**Desired Outcomes/Evaluation Criteria—Client Will****Spiritual Health NOC**

Verbalize increased sense of self-concept and hope for future.  
Discuss beliefs and values about spiritual issues.  
Verbalize acceptance of self as being worthy.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Spiritual Support NIC</b>	
<i>Independent</i>	
Determine client's religious or spiritual orientation, current involvement, and presence of conflicts.	Provides baseline for planning care and accessing appropriate resources.
Establish environment that promotes free expression of feelings and concerns. Provide calm, peaceful setting when possible.	Promotes awareness and identification of feelings so they can be dealt with.
Listen to client's and SO's reports or expressions of anger, concern, alienation from God, and/or belief that situation is a punishment for wrongdoing.	Helpful to understand client's and SO's point of view and how they are questioning their faith in the face of tragedy.
Note sense of futility, feelings of hopelessness and helplessness, and lack of motivation to help self.	These thoughts and feelings can result in the client feeling paralyzed and unable to move forward to resolve the situation.
Listen to expressions of inability to find meaning in life or reason for living. Evaluate for suicidal ideation.	May indicate need for further intervention to prevent suicide attempt.
Determine support systems available to client and SO(s).	Presence or lack of support systems can affect client's recovery.
Ask how you can be most helpful. Convey acceptance of client's spiritual beliefs and concerns.	Promotes trust and comfort, encouraging client to be open about sensitive matters.
Make time for nonjudgmental discussion of philosophical issues or questions about spiritual impact of events and current situation.	Helps client to begin to look at basis for spiritual confusion. Note: There is a potential for care provider's belief system to interfere with client finding own way. Therefore, it is most beneficial to remain neutral and not espouse own beliefs.
Discuss difference between grief and guilt and help client to identify and deal with each, assuming responsibility for own actions and expressing awareness of the consequences of acting out of false guilt.	Blaming self for what has happened impedes dealing with the grief process and needs to be discussed and dealt with.
Use therapeutic communication skills of reflection and active-listening.	Helps client find own solutions to concerns.
Discuss use of, and provide opportunities for, client and SO to experience meditation, prayer, and forgiveness. Provide information that anger with God is a normal part of the grieving process.	Can help to heal past and present pain.
Assist client to develop goals for dealing with life situation.	Enhances commitment to goal, optimizing outcomes and promoting sense of hope.
<i>Collaborative</i>	
Identify and refer to resources that can be helpful, such as pastoral or parish nurse, religious counselor, crisis counselor, psychotherapy, and Alcoholics or Narcotics Anonymous.	Specific assistance to resolve life stressors such as relationship problems, substance use, or suicidal ideation is important to advance recovery process.
Encourage participation in support groups.	Discussing concerns and questions with others can help client resolve feelings.

## NURSING DIAGNOSIS: risk for Post-Trauma Syndrome

### Possibly Evidenced By

Event outside the range of usual human experience; perceives event as traumatic  
Exposure to disaster, epidemic, event involving multiple deaths  
Serious threat or injury to self or loved ones  
Displacement from/destruction of one's home  
Exaggerated sense of responsibility; survivor role

### Desired Outcomes/Evaluation Criteria—Client/Caregivers Will

#### Personal Resiliency NOC

Express own feelings and reactions openly, avoiding projection.  
Demonstrate ability to deal with emotional reactions in an individually appropriate manner.

#### Anxiety Level NOC

Report absence of physical manifestations such as pain, nightmares, flashbacks, or fatigue associated with the event.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Crisis Intervention NIC</b> <i>Independent</i> Determine involvement in event—survivor, SO, and family, rescue or aid worker, healthcare provider, or family member of responder.	All those concerned with a traumatic event are at risk for emotional trauma and have needs related to their situation and involvement in the event. Note: Close involvement with victims or survivors affects individual responses and may prolong emotional suffering.
Evaluate life factors and stressors currently or recently occurring, such as displacement from home due to catastrophic event—illness, injury, natural disaster, or terrorist attack. Identify how client's past experiences may affect current situation.	Affects client's reaction to current event and is basis for planning care and identifying appropriate supports and resources.
Listen for comments of taking on responsibility such as "I should have been more careful . . . or gone back to get her."	Indicators of "survivor's guilt" and blaming self for actions that can delay recovery and impair general well-being.
Identify client's current coping mechanisms.	Noting positive or negative skills provides direction for care.
Determine availability and usefulness of client's support systems—family, social, and community.	Family and others close to the client may also be at risk and require assistance to cope with the trauma.
Provide information about signs and symptoms of post-trauma response, especially if individual is involved in a high-risk occupation.	Awareness of these factors helps individual identify need for assistance when they occur.
Identify and discuss client's strengths as well as vulnerabilities.	Provides information to build on for coping with traumatic experience.
Evaluate individual's perceptions of events and personal significance, for example, a rescue worker trained to provide lifesaving assistance but recovering only dead bodies.	Events that trigger feelings of despair and hopelessness may be more difficult to deal with and require long-term interventions.
Provide emotional and physical presence by sitting with client and SO and offering solace.	Strengthens coping abilities.
Encourage expression of feelings. Note whether feelings expressed appear congruent with events experienced.	Initially client may feel need to talk about the incident repeatedly. Incongruencies may indicate deeper conflict and can impede resolution.
Note presence of nightmares, reliving the incident, loss of appetite, irritability, numbness and crying, and family or relationship disruption.	These responses are normal in the early postincident time frame. If prolonged and persistent, they may indicate need for more intensive therapy.
Provide a calm, safe environment.	Helps client deal with the disruption in personal life.
Encourage and assist client in learning stress management techniques.	Promotes relaxation and helps individual exercise control over self and what has happened.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Monitor coworkers and volunteers for secondary traumatic stress and compassion fatigue. Model positive coping skills, optimism, appropriate humor.	Recognition of stress response in care providers/volunteers allows for timely promotion of techniques to support resilience and the ability to positively respond to adversity, facilitating one's healthy adjustment after trauma (Charney, 2004; Turner, 2014).
<b>Collaborative</b>	
Recommend participation in debriefing sessions that may be provided following major disaster events.	Dealing with the stresses promptly may facilitate recovery from event and prevent exacerbation.
Identify employment and community resource groups to support individual resilience	Provides opportunity for ongoing support to deal with recurrent feelings related to the trauma.
Administer medications, as indicated, such as the following: Antipsychotics, for example, phenothiazines such as chlorpromazine (Thorazine) and haloperidol (Haldol)  Carbamazepine (Tegretol)	Low doses may be used for reduction of psychotic symptoms when loss of contact with reality occurs, usually for clients with especially disturbing flashbacks.  Used to alleviate intrusive recollections and flashbacks, impulsivity, and violent behavior.

## NURSING DIAGNOSIS: **ineffective community Coping**

### May Be Related To

Exposure to disaster (e.g., earthquakes, floods, wild fires, reemerging infectious agents, terrorist activity)  
Insufficient community resources (e.g., housing, healthcare, clean water, transportation)  
Inadequate resources for problem-solving (e.g., disaster planning systems)

### Possibly Evidenced By

Deficient community participation; community does not meet expectations of its members  
Perceived community vulnerability/powerlessness; excessive community conflict  
Excessive stress  
Elevated community illness rate

### Desired Outcomes/Evaluation Criteria—Community Will

#### Community Competence NOC

Recognize negative and positive factors affecting community's ability to meet its own demands or needs.  
Identify alternatives to inappropriate activities for adaptation and problem-solving.  
Report a measurable increase in necessary or desired activities to improve community functioning.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Community Disaster Preparedness NIC</b>	
<b>Independent</b>	
Evaluate community activities as related to meeting collective needs within the community itself and between the community and the larger society. Note immediate needs, including healthcare, food, shelter, and funds.	Provides a baseline to determine community needs in relation to current concerns or threats.
Note community reports of functioning, including areas of weakness or conflict.	Provides a view of how the community itself sees these areas.
Identify effects of related factors on community activities.	In the face of a current threat, local or national, community resources need to be evaluated, updated, and given priority to meet the identified need.
Determine availability and use of resources. Identify unmet demands or needs of the community.	Information necessary to identify what else is needed to meet the current situation.
Determine community strengths.	Promotes understanding of the ways in which the community is already meeting the identified needs.
Encourage community members and groups to engage in problem-solving activities.	Promotes a sense of working together to meet the needs.
Participate in developing a plan jointly with the members of the community to address immediate needs.	Deals with deficits in support of identified goals.

(continues on page 992)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Create plans managing interactions within the community itself and between the community and the larger society.	Meets collective needs when the concerns or threats are shared beyond a local community.
Make information accessible to the public. Provide channels for dissemination of information to the community as a whole, including print media, radio and television, community bulletin boards, social media, Internet resources, speakers bureau, reports to committees, councils, or advisory boards.	Readily available accurate information can help citizens make informed decisions to deal with the situation.
Make information available in different modalities and geared to differing educational levels and cultures within the community.	Using languages other than English and making written materials accessible to all members of the community will promote understanding.
Seek out and evaluate needs of underserved populations.	The homeless and those residing in lower-income areas may have special needs requiring additional resources.

### NURSING DIAGNOSIS: **readiness for enhanced community Coping**

#### Possibly Evidenced By

Expresses desire to enhance problem-solving for identified issues  
 Expresses desire to enhance communication among community members and between groups and larger community  
 Expresses desire to enhance community planning for predictable stressors

#### Desired Outcomes/Evaluation Criteria—Community Will

##### Community Competence NOC

Identify positive and negative factors affecting management of current and future problems or stressors.  
 Have an established plan in place to deal with various contingencies.  
 Report a measurable increase in ability to deal with potential events.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Program Development NIC</b>	
<i>Independent</i>	
Review community plans to monitor for and deal with untoward events.	Provides a baseline for comparison of preparedness with other communities and developing plan to address concerns.
Assess effects of related factors on management of problems or stressors.	Identifies areas that need to be addressed to enhance community coping.
Determine community strengths and weaknesses. Identify limitations in current pattern of community activities that can be improved through adaptation and problem-solving.	Plan can be built on strengths, and areas of weakness can be addressed.
Evaluate community activities as related to management of problems or stressors within the community itself and between the community and the larger society.	Disasters occurring in the community or the country affect the local community and need to be recognized and addressed.
Define and discuss current needs and anticipated or projected concerns.	Agreement on scope and parameters of needs is essential for effective planning.
Identify and prioritize community goals.	Helps to bring the community together to meet a common concern or threat. Helps maintain focus and facilitates accomplishment.
Promote community awareness about the problems of design of buildings, equipment, transportation systems, and workplace practices that may compound disaster or impact disaster response.	Provides opportunity for making changes that promote safety.
Identify available resources—persons, groups, financial, governmental, as well as other communities.	Important to work together to meet goals. Major catastrophes affect more than local community, and communities need to work together to deal with and accomplish recovery.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Seek out and involve underserved and at-risk groups within the community.	Supports communication and commitment of community as a whole.
Assist the community to form partnerships within the community and between the community and the larger society.	Promotes long-term developmental growth of the community.
Establish mechanism for self-monitoring of community needs and evaluation of efforts.	Facilitates proactive rather than reactive responses by the community.
Participate in exercises and activities to test preparedness.	Provides opportunities to verify appropriateness of plans and problem-solve deficiencies.
Use multiple formats—TV, radio, print media, billboards, computer bulletin boards, social media, speakers bureau, and reports to community leaders and groups on file that are accessible to the public.	Keeps the community informed and involved regarding plans, needs, and outcomes of tests of the plans.

## PEDIATRIC CONSIDERATIONS

### I. Challenges

- a. Undergoing medical treatment can be emotionally and psychologically difficult for the child (infant through adolescent) and his or her family.
- b. Children are not “small adults” and require child-friendly care with adaptation of interventions dependent on maturation of body systems and organ function and the child’s age and developmental level (London, 2007).
  - i. Growth—generally follows a predictable pattern influenced by gender, heredity, environmental factors (such as nutrition), and cultural practices
  - ii. Development—each child’s maturational pattern is unique; however, the sequence for acquisition of skills is uniform in children, essentially proceeding from the head down and from the center of the body out to the extremities.
- c. Special approaches are required to meet the physical, emotional, social, spiritual, and cultural needs of the hospitalized child and his or her family.
  - i. Child-sized equipment
  - ii. Diversional activities—age-appropriate play rooms, games, arts, recreation
  - iii. Learning opportunities—age-appropriate print and visual teaching tools, tutoring during prolonged hospitalization
  - iv. Family-centered care—inclusion of all members, as appropriate, with consideration of sociocultural and spiritual factors

### II. Developmental Factors Relating to Hospitalization (The Children’s Hospital of Philadelphia, n.d.; Morgan Stanley Children’s Hospital of New York Presbyterian, 2008)

- a. Infant—birth to 12 months
  - i. Just learning to make sense of the world; child can become very unsettled when cared for by multiple or different providers.
  - ii. Cannot understand how various procedures and treatments that he or she perceives to “hurt” can actually produce recovery or make them well.
  - iii. From about age 6 months and older, child can become very afraid if parents leave him or her.

- b. Toddler—12 to 36 months
  - i. Issues of separation, rather than being ill, can be the major stress for child if required to stay in hospital without parent or familiar caregiver.
  - ii. Has no concept or understanding of what is happening when they are ill
  - iii. Does not understand time and space so all this can be very frightening for them
- c. Preschool—3 to 5 years
  - i. Fear of the unknown and being left alone are major concerns.
  - ii. Have limited ability to distinguish fantasy from reality
  - iii. Tend to misunderstand words they hear, leading to misconceptions
  - iv. May view hospitalization as a punishment—fearing needles, body mutilation, or loss of function
- d. School-age child—6 to 11 years
  - i. Almost all school-age children will have seen and heard about illness and hospitals on TV.
  - ii. May have seen people “die” in hospital and know about cancer and other illnesses that can cause children to die
  - iii. Need to know what will happen to them and that they will not die from this illness—may be too frightened to ask about this themselves
  - iv. Often misunderstand what they overhear; require opportunities to ask questions
- e. Adolescent—12 to 18 years
  - i. Understands what causes illness and how it affects the body
  - ii. Fears separation from peers and group activities
  - iii. Hospitalization represents a loss of control over almost all areas of life, even the most basic aspects—when the teen eats, sleeps, or uses the bathroom, coupled with a loss of privacy at a time when self-consciousness is peaking.
  - iv. May express anger or indifference to mask feelings of fear
  - v. May feel bothered by frequent examinations by different professionals

(continues on page 994)

- vi. Hospitalization represents a challenge to all teens, especially teens from ethnic, religious, or cultural minority groups.

### III. Statistics

- a. Nearly 5.9 million children in the United States aged 0 to 17 were hospitalized in 2012, of which 3.9 million were neonatal stays and 104,700 were maternal stays for teens. (Healthcare Cost and Utilization Project [HCUP], 2014). In 2014, the top 5 admission diagnoses were mood disorders, asthma, pneumonia, acute bronchitis, and epilepsy/convulsions (McDermott et al, 2017).

For additional information concerning pediatric concerns, see Pediatric Pearls (PP) in the following care plans: Appendectomy; Brain Infections: Meningitis and Encephalitis; Burns; Chronic Obstructive Pulmonary Disease (COPD) and Asthma; Diabetes Mellitus and Diabetic Ketoacidosis; Disaster Considerations; Eating Disorders: Anorexia Nervosa/Bulimia Nervosa; Obesity; Fractures; Inflammatory Bowel (IBD); Ulcerative Colitis, Crohn's Disease; Pneumonia; Seizure Disorders; Substance Use Disorders; and Sickle Cell Crisis.

## G L O S S A R Y

**Development:** The qualitative increase in a child's capabilities or function, attainment or mastery of skills.

**Growth:** Increase in physical size and internal development as measured by multiple factors, such as height, weight, blood pressure, and sexual maturation, as well as the number of words in vocabulary.

**Major Theories of Development (London, 2007):**

**Behaviorism:** The research of animal behaviorists was applied to children and demonstrated that behaviors can be elicited by positive reinforcement or extinguished by negative reinforcement. Application of theory to hospitalization—repetition of desired behaviors can be encouraged by providing positive reinforcement for child's efforts.

**Ecologic theory:** Although controversy exists about heredity (nature) versus environment (nurture) and which one has more influence in human development, this theory recognizes the effect of both through mutual interactions between the child and the various levels of the environment (from close to remote) in all of life's settings. Application of theory to hospitalization—use of tool based on this theory to assess child's interface with varied levels of the environment identifies areas of strength that can help with addressing individual challenges or areas that are nonsupportive.

**Erikson's theory of psychosexual development:** Describes psychosocial stages during eight periods of human life with a particular challenge that is needed for healthy development to occur. Application of theory to hospitalization—interrupts usual support provided by family and peers and adds a situational crisis to the normal developmental crisis experienced by the child.

**Freud's theory of psychosexual development:** Early childhood experiences form the unconscious motivation for actions in later life. Application of theory to hospitalization—defensive mechanisms, such as regression and repression, may be used by the child to cope with excess anxiety, and the crisis of illness can interfere with normal developmental processes.

**Kohlberg's theory of moral development:** Using Piaget's cognitive theory as a basis for moral development, three levels of moral reasoning—preconventional, conventional, and postconventional—were identified with associated age ranges. Application of theory to hospitalization—based

on stage of development, decisions made by the child may reflect a desire to avoid punishment, to please others, or to present a sense of social responsibility. This provides some direction to care providers as they present information to the child to assist them in the decision-making process.

**Piaget's theory of cognitive development:** The child's view of the world is influenced largely by age and maturational ability and matures naturally. Application of theory to hospitalization—level of cognitive development and thought processes affects choice of approaches when providing appropriate stimulation and creating teaching plans for the child.

**Resiliency theory:** A child's characteristics and how these traits interact with the environment determine his or her resiliency or ability to use healthy responses even in adverse situations. In the face of a crisis, the child and the family have protective characteristics that provide strength and risk factors or characteristics that magnify challenges. Application of theory to hospitalization—providing positive reinforcement for protective characteristics—encourages continuation of desired behaviors that can be used to support the period of adjustment and facilitate adaptation to change. Identification of risk factors provides an opportunity to target interventions and teaching activities to assist family and child to deal more effectively with the challenge and increase their resiliency.

**Social learning theory:** Children learn attitudes, beliefs, customs, and values through their social contacts with adults and other children, and they model the behavior they see. Application of theory to hospitalization—the provision of positive role model, such as a peer experiencing a similar situation, facilitates learning and child's cooperation with interventions.

**Temperament theory:** The child both influences, and is influenced by, the environment and has innate qualities of personality or certain patterns of temperament that he or she brings to daily life. Application of theory to hospitalization—understanding the child's temperament—provides opportunities to alter or manipulate the environment to meet the child's needs and maximize the experience.

**CARE SETTING**

Any setting in which nursing contact with children occurs and care is provided.

**CLIENT ASSESSMENT DATABASE**

Data depend on the specific pathology necessitating therapeutic interventions.

\*\*\*\*Assessment Factors—in addition to routine assessment of current condition or comorbidities

SUBJECTIVE	OBJECTIVE
<b>INDIVIDUAL</b> <ul style="list-style-type: none"> <li>Perception of body and its functions in health, illness, and in this situation</li> <li>Emotional reactions in feeling or sensory terms; for example, client states, “I feel scared.”</li> <li>Food and eating concerns</li> <li>Sleep patterns</li> <li>Lifestyle concerns requiring consideration—dietary preferences and problems; sexual identity and activity; beliefs and practices surrounding alcohol, tobacco, and other drugs; other community (e.g., school, religious environment, home of record [e.g., nuclear family, foster care, homeless])</li> </ul>	<ul style="list-style-type: none"> <li>Age, developmental level, gender identity</li> <li>Personality, temperament</li> <li>Patterns of communication with significant others (SOs)</li> <li>Behavior when anxious, afraid, impatient, withdrawn, or angry</li> <li>Emotional response to current treatment or hospitalization</li> <li>How child experiences illness versus reality of situation</li> </ul>
<b>SIGNIFICANT OTHERS</b> <ul style="list-style-type: none"> <li>Nuclear family, extended family; peer group, friends</li> <li>Family developmental cycle</li> <li>Child's role in family tasks and functions</li> <li>How are SOs affected by the illness and prognosis?</li> </ul>	<ul style="list-style-type: none"> <li>Interaction processes within the family</li> </ul>
<b>SOCIOECONOMIC</b>	<ul style="list-style-type: none"> <li>Social class, value system</li> <li>Social acceptability of current situation</li> </ul>
<b>CULTURAL</b> <ul style="list-style-type: none"> <li>Ethnic background, heritage, and residence</li> <li>Family beliefs regarding caring and curing</li> <li>Family health-seeking behaviors, illness referral system</li> <li>Family values related to health and treatment</li> <li>Cultural factors related to illness in general and to pain response</li> </ul>	
<b>DISEASE/CONDITION</b> <ul style="list-style-type: none"> <li>Past experience with illness, hospitalization, healthcare systems and providers</li> <li>Family and child expectations if illness is terminal</li> </ul>	<ul style="list-style-type: none"> <li>Response of child and family to situation or condition requiring treatment</li> <li>Nature of condition—acute, chronic, recurrent</li> <li>Emotional response to current treatments</li> <li>Availability and use of resources</li> </ul>

**NURSING PRIORITIES**

- Enhance level of comfort and minimize pain.
- Reduce anxiety and fear.
- Provide growth-promoting environment for child and parent(s).
- Prevent or minimize complications.

**DISCHARGE GOALS**

- Pain relieved or controlled.
- Child and family dealing appropriately with current situation.
- Safe environment maintained.
- Plan in place to meet needs after discharge.

## NURSING DIAGNOSIS: acute/chronic Pain

### May Be Related To

Injuring agents—biological, chemical, physical

### Possibly Evidenced By

Self-report of pain intensity/characteristics using standardized scale/instrument; evidence of pain using standardized pain behavior checklist for those unable to communicate verbally  
Expressive behavior (e.g., restlessness, moaning, crying, irritability)  
Appetite change, anorexia; alteration in sleep pattern  
Positioning to ease pain  
Change in physiological parameter (acute pain)

### Desired Outcomes/Evaluation Criteria—Child Will

#### Pain Level NOC

Report or indicate pain is relieved or controlled.  
Manifest decreased restlessness and irritability.  
Demonstrate age-appropriate blood pressure (BP), pulse, and respiratory rates.

#### Pain Disruptive Effects NOC

Participate in usual activities within level of ability.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Pain Management: Acute/Chronic NIC</b> <i>Independent</i>	
Perform routine comprehensive pain assessment, including location, characteristics, onset, duration, frequency, quality, and severity using some type of rating scale, such as numbers or visual analog, facial expressions, or color scale.	Assessment of children involves observational skills and may require enlisting the aid of parent or caregiver to clarify cues and verbalizations. Choice of rating scale is dependent on age and developmental level (Suresh, 2009).
Accept child's description of pain, noting precipitating, exacerbating, and relieving factors.	Pain is subjective and cannot be experienced by others. Note: In presence of chronic pain situation, use of a pain diary may be appropriate for adolescents (Suresh, 2009).
Investigate changes in frequency or description of pain.	May signal worsening of condition or development of complications.
Observe for guarding, rigidity, crying, and restlessness.	Nonverbal expressions, body movement, and behavioral state may signal pain or changes in pain severity, especially in infants and younger children (Suresh, 2009).
Monitor heart rate, BP using correctly sized cuff, and respiratory rate, noting age-appropriate normals and variations.	Changes in autonomic responses may indicate increased pain before child verbalizes. Note: Autonomic responses change with acute pain, not chronic pain. BP may be lower than normal or higher than normal.
Note location and type of surgical incisions or trauma.	Influences degree and severity of pain manifestations.
Provide comfort measures, such as holding, repositioning, back rub, and use of breathing or guided visualization relaxation techniques, as indicated.	Nonpharmacological pain management promotes relaxation; may reduce level of pain and enhance coping.
Identify ways to avoid or minimize pain, such as splinting surgical incisions during coughing, sleeping on a firm mattress, or wearing brace on sprains.	Many factors may reduce pain intensity based on specific situation. Child can quickly learn and use such pain management techniques, enhancing sense of control as well as comfort.
Encourage sleep and rest periods.	Helps reduce fatigue and enhances coping ability.
Encourage diversional activities such as TV, music, reading, playing computer/video or table games, and texting friends.	Helps distract child's attention from pain and reduces tension.
Review procedures and expectations and tell child when it will hurt. Provide distraction during painful procedures, such as deep breathing or counting, or looking at something that interests child.	Although the procedure may still be stressful, child will find it easier to handle if he or she knows what to expect and has developed coping strategies.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Encourage expression of feelings about pain.	Can relieve anxiety and help reduce intensity of pain.
Suggest parent and caregiver be with child during procedures, as possible.	Provides comforting presence.
<b>Collaborative</b>	
Collaborate in treatment of underlying conditions or disease process.	Treating cause, when possible, can eliminate pain.
Administer medications, such as opioid and nonsteroidal analgesics, as indicated. Use multiple routes to deliver analgesia, such as oral, nebulized, transdermal, or patient-controlled analgesia (PCA), as indicated by current situation.	Depending on the cause and type of pain, as well as its chronicity, various means of pain management may be needed to overcome or control pain.

NURSING DIAGNOSIS: Anxiety/Fear
<b>May Be Related To</b>
Stressors; interpersonal transmission or contagion Threat to current status/death; unmet needs Separation from support system; unfamiliar setting
<b>Possibly Evidenced By</b>
Apprehensiveness; distress; feeling of fear Restlessness; increase in tension; poor eye contact Worried about change in life event; decrease in self-assurance Alteration in sleep pattern; fatigue; nausea, anorexia Changes in vital signs
<b>Desired Outcomes/Evaluation Criteria—Child Will</b>
<b>Anxiety Level [or] Fear Level: Child NOC</b>
Appear relaxed and report or demonstrate relief from somatic manifestations of anxiety. Demonstrate a decrease in somatic complaints and physical symptoms when faced with stressful situations such as impending separation from SO.
<b>Anxiety Self-Control NOC</b>
Engage in age-appropriate activities in absence of parent or primary caregiver without fear or distress noted.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Anxiety Reduction NIC</b>	
<b>Independent</b>	
Establish an atmosphere of calmness, trust, and genuine positive regard.	Trust and unconditional acceptance are necessary for satisfactory therapeutic relationship. Calmness is important because anxiety is easily transmitted from one person to another, and children are often adept at sensing changes in the moods of adults around them.
Prepare child for activities and procedures. Provide explanations in language appropriate for age. Use terms familiar to child, such as for care activities—"walk" instead of "ambulate"—or procedures—"take a picture" instead of "fluoroscope." Provide opportunity for client to ask questions, observe or touch equipment as appropriate.	Accurate and age-appropriate communication promotes trust and creates an atmosphere where child feels free to ask questions. Based on child's developmental level, tour of facility or surgical suite and observation of "machinery" in action may help reduce concerns regarding the unknown. Note: Children may become frightened of things they cannot articulate.
Ensure child of his or her safety and security—listen to child, identify needs, and be available for support.	Strange people and surroundings, changes in routine, and loss of control in situation create anxiety and can be very frightening. Children may believe that situation is punishment for some wrongdoing—imagined or real—on their part. Providing information and being available can be reassuring.

(continues on page 998)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Be honest with child and parents/caregiver by saying, "Yes, this will hurt and I will help you manage it."	Promotes trust and belief that child will not be left alone to deal with situation.
Refrain from conversations unrelated to child in his or her presence or failing to include child in conversations regarding him or her.	Ignoring the child or talking about, instead of to, the child or allowing child to overhear partial or unrelated conversations may be very stressful and result in child imagining things that are incorrect.
Maintain home routines whenever possible. Encourage child and parents to bring transitional object from home, such as familiar toys, handheld computer games or digital music player, special pillow or blanket, some favorite pictures, or posters, if hospitalized.	Use of age-appropriate object enhances sense of security when child or adolescent is hospitalized or in treatment setting.
Provide consistency of care providers.	Becoming acquainted with care provider enhances sense of security, facilitates communication, and lessens anxiety.
Promote child and family contact and interaction. Encourage parents, and child as appropriate, to participate in care planning and care provision.	Family involvement in activities promotes continuity of family unit, provides opportunity to learn and practice new skills, and enhances coping skills.
Emphasize importance of staff and family giving verbal prompts in anticipation of absences. Provide honest information about leaving and returning.	Avoidance of these issues increases the likelihood of anxiety responses when separation occurs.
Help family support child emotionally by being available and active-listening.	Conveys acceptance of child and confidence in ability to cope with situation.
Encourage contact with peers via phone, texting, social network sites, online chats, or visits, as appropriate.	Helps child stay connected with friends and life outside hospital.
Provide child with age-appropriate choices, when possible.	Promotes sense of control, demonstrates regard for individual.
Schedule ample time for play and age-appropriate diversions. Use play materials, such as puppets, doll house, doctor/nurse kits, fairytale stories, clay, coloring book, and so on.	Promotes normalcy and helps divert attention from situation. Play therapy enables child to explore conflicts, express fears, and release tension.
Engage in exercise program as appropriate to situation.	Provides physical outlet for energy, releasing tension. May stimulate release of endorphins, decreasing anxiety and enhancing child's ability to deal with illness and situation.

#### **Collaborative**

Administer medications, as indicated.

Mild sedation can be effective in ameliorating symptoms of anxiety and enhancing child's receptiveness to therapeutic regimen.

## NURSING DIAGNOSIS: **Activity Intolerance**

#### **May Be Related To**

Immobility; physical deconditioning  
Imbalance between oxygen supply/demand

#### **Possibly Evidenced By**

Fatigue, generalized weakness; exertional discomfort or dyspnea  
Abnormal heart rate or BP response to activity

#### **Desired Outcomes/Evaluation Criteria—Child Will**

#### **Endurance NOC**

Participate in customary activities at desired level.  
Report or display absence of fatigue.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Activity Therapy [NIC]</b>	
<i>Independent</i>	
Note presence of acute or chronic illness (e.g., heart failure, pulmonary disorders, anemias, cancers).	Conditions associated with increased risk of impaired tolerance for activity related to oxygen supply and demand, resulting in weakness and fatigue.
Ascertain child's usual level of activity, taking into account age and developmental level.	Establishes baseline in order to determine needed interventions and to assess progress of recovery.
Determine usual sleep and rest routine and any bedtime rituals or security objects. Plan care with adequate rest periods.	Attempting to maintain usual sleep routines promotes rest and maximizes energy and endurance.
Adjust activities, reducing intensity level or discontinuing activities, as needed. Assist with activities of daily living (ADLs) and promote exercise, as indicated.	Protects child from injury and enhances ability to participate in activity to improve strength.
Promote participation in individually appropriate recreational and diversional activities.	Enhances sense of well-being and expectation of return to usual activities.
Promote optimal mobility, providing safe transport such as wagon, child-size wheelchair, or walker.	Provides normalcy to child, who is not accustomed to inactivity, and will help reduce complications associated with immobility.
Monitor response to activity, including BP, pulse, respiratory rate, skin color, and behavior.	Helps identify and monitor degree of fatigue and potential for complications.
<i>Collaborative</i>	
Collaborate in treatment of underlying condition.	Treating or curing underlying condition can restore child's energy and ability to carry on desired activities.
Provide and monitor response to oxygen administration via appropriate route and effects of medication.	Oxygen may be needed to improve tolerance to activity and treat underlying cause for fatigue. High-flow oxygen via nonrebreather mask is ideal if child can tolerate it. Blow-by oxygen can provide some benefit if child refuses to wear mask.
Refer to physical and occupational therapists.	Helpful to develop activity and exercise programs to meet individual and family needs.

### NURSING DIAGNOSIS: **risk for delayed Development [Growth]**

#### Possibly Evidenced By

Chronic illness; otitis media; substance misuse  
Economically disadvantaged; inadequate nutrition; maladaptive feeding behaviors  
Congenital disorder; prematurity  
Insufficient prenatal care  
Behavior disorder; brain injury; lead poisoning; seizure disorder; presence of abuse

#### Desired Outcomes/Evaluation Criteria—Child Will

##### **Child Development: [specify age group] NOC**

Perform motor, social, and/or expressive skills typical of age group within scope of present capabilities.  
Demonstrate weight and growth stabilization or progress toward age-appropriate size.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Development Enhancement: Child [or] Adolescent [NIC]</b>	
<i>Independent</i>	
Determine existing factors or condition(s) that could contribute to growth or development deviation, such as chronic illness, substance use or abuse, familial history of pituitary tumors, Marfan's syndrome, and genetic anomalies.	Plan of care will be based on individual factors present, immediacy of threat, and potential long-term complications. Note: Use of tobacco, alcohol, or other drugs are major healthcare concerns for children.

(continues on page 1000)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Determine child's birth weight and length and compare present growth with norms.	Identifies the child's status compared with other children of the same age.
Note chronological age and familial factors, such as body build and stature, stage of sexual maturity. Review expectations for current height and weight percentiles and degree of deviation.	Aids in determining growth expectations.
Measure developmental level using age-appropriate tests, such as the Denver Developmental Screening Test. Note reported losses or alterations in functional level.	Provides comparative baseline and basis for choosing developmentally appropriate interventions.
Determine child's cognitive and perceptual level, such as grade level in school. Note behavioral reaction to environment and stimuli, such as withdrawal or aggression.	Illness or injury can lead to a temporary increase in level of dependency and a decline in functional level. Although this may not be of major concern for the short term, chronic and recurrent conditions may delay acquisition of important developmental milestones.
Note severity and pervasiveness of situation. For example, is the child showing effects of long-term physical or emotional abuse or neglect versus experiencing recent-onset situational disruption or inadequate resources during period of crisis or transition?	Problems existing over a long period may have more severe effects and require longer course of treatment to reverse.
Determine occurrence and frequency of significant stressful events in the child's life, including losses, separation, and environmental changes, such as abandonment, divorce, death of parent or sibling, and relocation.	Lack of resolution or repetition of stressor can have a cumulative effect over time and result in regression in, or deterioration of, functional level.
Discuss nature and effectiveness of parenting and caregiving activities, noting inadequate, inconsistent, unrealistic, or insufficient expectations as well as lack of stimulation, limit setting, or responsiveness.	Assessment of parenting and potential for conflict and negative interaction between parent or caregiver and child identifies interventions needed to maximize care.
Provide parents with information regarding normal growth and development, as appropriate, including pertinent reference materials.	Helps parents understand potential changes in relation to current illness or problem.
Identify realistic goals with child and parents. Discuss actions to take to avoid or minimize preventable complications.	Provides anticipatory guidance. Increases probability of reaching goals and managing situation more effectively. Can enhance sense of control and independence.
Encourage self-care activities, as appropriate, such as feeding, grooming, and playing. Provide privacy when desired and when privacy is safe for child.	Promotes independence and maintenance of self-esteem.
<b>Collaborative</b> Assist with therapy to treat or correct underlying conditions, such as Crohn's disease, cardiac problems, or renal disease; endocrine problems, such as hypothyroidism, type 1 diabetes mellitus, or growth hormone abnormalities; and genetic or intrauterine growth retardation, infant feeding problems, or nutritional deficits.	Illness, hospitalization, treatments, and separation from parents and family have a negative effect on physical and psychological growth and development.
	Multidisciplinary team involvement increases likelihood of a well-rounded plan of care that meets child's special and varied needs.
	Although acute situations may be readily resolved with limited support and few ill effects, chronic or recurrent conditions require many resources to maximize growth potential of child and family.
	Prevents child from falling behind in studies and provides sense of normalcy during prolonged illness or hospitalization.

**NURSING DIAGNOSIS:** risk for imbalanced Nutrition: less than body requirements**Possibly Evidenced By**

Insufficient dietary intake  
Inability to ingest or digest food or absorb nutrients because of biological, psychological, or economic factors

**Desired Outcomes/Evaluation Criteria—Child Will****Nutritional Status NOC**

Ingest nutritionally adequate diet for age, activity level, and metabolic demands.  
Demonstrate stable weight or progressive weight gain toward goal.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Nutrition Management NIC</b>	
<i>Independent</i>	
Identify child at risk for malnutrition, such as with intestinal surgery, hypermetabolic states, restricted intake, and/or prior nutritional deficiencies, food refusal.	Provides opportunity for timely intervention.
Determine ability to chew, swallow, and taste. Note presence of conditions affecting food intake, such as nausea and vomiting; food intolerances or allergies; lactose intolerance, cystic fibrosis, diabetes, inflammatory bowel diseases, or eating disorders (including anorexia and overeating).	These factors can affect specific dietary choices, desire to eat, and/or ingestion and digestion of nutrients.
Ascertain child's oral health, noting presence and condition of teeth, impairment of oral mucous membranes (e.g., painful lesions, enlarged tonsils), or problems with facial structures (e.g., facial/jaw trauma, cleft palate, presence of ET tube).	Various conditions of the mouth and facial structures can impair child's ability and desire to ingest food.
Determine child's current nutritional status using age-appropriate measurements, including weight and body build, strength, activity level, and sleep and rest cycles.	Identifies individual nutritional needs and provides comparative baseline.
Auscultate bowel sounds. Note characteristics of stool, including color, amount, and frequency of bowel movements.	Provides information about digestion and bowel function and may affect choice and timing of feeding.
Elicit information from child/parent regarding typical daily food intake, determining foods and beverages normally consumed. Note types of snacks. Discuss eating habits and food preferences—likes and dislikes.	Baseline information to determine adequacy of intake. Knowledge of child's specific likes and dislikes may be helpful in meeting child's nutritional needs during a time when appetite is suppressed or child has no interest in food.
Determine whether infant is breastfed or formula-fed and typical pattern of feedings during a 24-hour period. Note type and amounts of solid foods infant or toddler eats.	Providing usual and typical feedings is important to infant well-being and early growth.
Determine psychological factors and cultural or religious desires or influences on dietary choices.	Dietary beliefs, such as vegetarianism, can affect nutritional intake. Usual ethnic food choices can improve a child's intake when appetite is poor.
Review drug regimen, noting potential side effects and possible interactions with other medications, over-the-counter (OTC) drugs, and herbs.	Timing of medication doses and interaction with certain foods can alter effect of medication or digestion and absorption of nutrients.
Discuss with parent what types of snacks (e.g., candy, other sweets, fruits/vegetables, and beverages) child eats or drinks.	Identifies what child eats in a typical day and can provide opportunity for teaching about healthy snacks when that is needed/desired.
Emphasize importance of well-balanced meals. Provide information regarding individual nutritional needs and ways to meet these needs within financial constraints. Avoid arguing over food choices.	Although nutritious intake is important, arguing over food is counterproductive. Providing age-appropriate guidelines to children as well as to parents or care provider may help them in making healthy choices. Note: Childhood obesity with associated long-term physical and psychological effects is a potential concern regardless of current weight.

(continues on page 1002)

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Clarify caregiver access to and use of resources, such as Supplemental Nutrition Assistance Program (SNAP); budget counseling; Women, Infants, and Children (WIC) program; community food bank; and/or other appropriate assistance programs.	May be necessary to improve child's intake and/or availability of food to meet nutritional needs.
<b>Collaborative</b>	
Establish a nutritional plan (with monitoring, when needed) that meets individual needs incorporating or limiting specific foods.	Certain medical conditions (e.g., diabetes, cancer, gluten allergy, malabsorption syndrome, anorexia) require special dietary considerations to manage symptoms or bring about healing.
Consult dietitian or nutritional team, as indicated.	Helps determine individual nutritional needs and therapeutic diet.
Review laboratory studies, such as serum albumin or prealbumin, transferrin, amino acid profile, iron, blood urea nitrogen (BUN), nitrogen balance studies, glucose, liver function, electrolytes, and total lymphocyte count.	Indicators of nutritional health and effects of nutrients in organ function.
Refer for dental hygiene care, nutritional counseling, or psychiatric or family therapy, as indicated.	May be needed to provide assistance, support, and direction for meeting nutritional needs not only in the present but for achieving long-term goals as well.
Refer to home-care resources when indicated by specific condition or illness.	Assists with initiation and supervision of home nutrition therapy when used.

### NURSING DIAGNOSIS: risk for Injury, physical Trauma, Suffocation, Poisoning

#### Risk Factors May Include

Extremes of age; alteration in cognitive functioning; emotional disturbance  
Disease or injury process; struggling with restraints or safety devices; absence of call-for-aid device  
Popped bottle in infant's crib; pacifier around infant's neck  
Insufficient knowledge of safety/poisoning precautions  
Immune or autoimmune dysfunction; malnutrition; exposure to pathogens

#### Possibly Evidenced By

(Not applicable, presence of signs and symptoms establishes an actual diagnosis)

#### Desired Outcomes/Evaluation Criteria—Child Will

#### Risk Control NOC

Be free of injury.

#### Caregiver/Parent—Will

Verbalize understanding of individual risk factors that contribute to possibility of injury.  
Take steps to correct identified risks and protect child from hazards.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Risk Surveillance NIC</b>	
<b>Independent</b>	
Note client's and SO's age, developmental stage, level of cognition, decision-making ability.	These factors are critical in assessing safety needs and evaluating client's or caregiver's ability to meet client's needs as discharge planning begins.
Identify individual risk factors in child's healthcare setting, including (1) physical needs (e.g., airway patency, therapeutic use of potentially toxic medications, invasive lines or procedures, exposure to latex products), (2) medical conditions (e.g., impaired cognitive, developmental, psychological, or neurological status), (3) environmental factors (e.g., exposure to safety hazards in healthcare setting [e.g., immobility, use of restraints/braces/casts], home, or community [including violence and substance use]).	Provides opportunity to modify environment and eliminate factors that place child at risk.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Provide healthcare within a culture of safety (e.g., adherence to nursing standards of care and facility safe-care policies):	Prevents errors resulting in child injury, promotes safety, and models safety behaviors to client/SO.
Provide appropriate level of supervision.	Promotes child's well-being and allows for timely intervention, when needed.
Initiate safety precautions as individually appropriate, such as bed in low position, padded side rails, infection precautions, floors clear of hazards, supervised use of mobility aids.	Preventing injuries and complications is a prime responsibility of parents and care providers.
Have age-appropriate equipment available, including properly sized BP cuff, intravenous (IV) catheters, airway adjuncts, and oxygen mask or hood; suction equipment, ventilator bag, low-flow IV pump, or warming devices.	Prevents treatment-related injuries and ensures availability of age- or size-appropriate life-saving equipment.
Monitor medication administration closely, paying careful attention to allergies, dosage measurements and conversions, side effects, and potential adverse effects. Use pediatric concentrations of medications when available.	Provides for effective therapeutic management, prevents overdose, and reduces risk for toxic reactions.
Note history of latex allergies or dermatitis. Avoid latex products while in facility care and instruct client/SO in ways to avoid recurrent exposure to latex products, including gloves, catheters, and tubing, when client requires those for postdischarge care.	Repeat exposure increases risk of developing sensitivity or serious adverse reactions to latex products.
Review home situation for safety hazards, especially when child has sustained some type of injury related to unsafe home environment.	Provides opportunity for teaching about factors that could promote a safer home environment or might identify need for more intensive interventions.
Ascertain client and caregiver knowledge of safety needs and injury prevention in child's play and sports setting.	Specific attention needs to be focused on childhood recreational and sports injuries, including impact of repeated concussions, which is often underestimated.
Provide written resources for parent or caregiver and age-appropriate handouts for child, including information about safety issues, such as immunizations, obesity, smoking, substance use, and safer sex practices.	Provides information for later review and self-paced learning.
Encourage parent/caregiver to learn cardiopulmonary resuscitation (CPR) and individually appropriate procedures or emergency interventions and responses, such as carrying an EpiPen.	Being prepared for emergencies promotes confidence for adults and children in their own ability to deal with their situation.
<b>Collaborative</b> Refer to home-care assistance, medical supplies, community safety and education programs, and resources, such as Family Effectiveness Training, as indicated.	Can provide additional opportunities for support for child safety, for improving parenting skills, and obtaining necessary equipment.

### NURSING DIAGNOSIS: **risk for imbalanced Fluid Volume**

#### Possibly Evidenced By

Extremes of age/weight; factors influencing fluid needs (e.g., vomiting, diarrhea, burns, sepsis)  
Treatment regimen (rapid or excessive fluid replacement); insufficient fluid intake/barrier to accessing fluid

#### Desired Outcomes/Evaluation Criteria—Child Will

##### Hydration NOC

Demonstrate adequate fluid balance as evidenced by stable vital signs, palpable pulses of good quality, normal skin turgor, moist mucous membranes; individually appropriate urinary output; lack of excessive weight fluctuation—loss or gain; and absence of edema.

##### Parent/Caregiver Will

##### Risk Control NOC

Verbalize understanding of child's fluid needs.  
Promote adequate age-appropriate fluid intake.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Fluid Management NIC</b>	
<b>Independent</b>	
Note potential sources of fluid loss and intake, presence of conditions such as diabetes or burns, recurrent blood draws, and use of total parenteral nutrition (TPN).	Causative and contributing factors for fluid imbalances.
Note child's age, size, weight, and cognitive abilities.	Affects ability to tolerate fluctuations in fluid level and ability to respond to fluid needs.
Monitor vital signs; color of palms, soles of feet, and mucous membranes; weight; skin turgor; breath sounds; urinary and gastric output; and hemodynamic measurements.	Indicators of hydration status. Note: Hypotension indicative of developing shock may not be readily observed in child until very late in the clinical course because of vasoconstriction.
Review child's intake of fluids.	Children often do not take in enough oral fluids to meet hydration needs.
Determine child's normal pattern of elimination and whether child is toilet trained.	Provides information for baseline and comparison. If child is in diapers, output may be determined by weighing diapers.
Determine whether child has problems with urination, such as urine retention, bedwetting, burning, or holding.	Evaluation of these issues is important for determining cause and treatment of underlying problem.
Note use of drainage devices such as nasogastric (NG) tube or wound drain and use of laxatives, enemas, or suppositories.	May increase fluid and electrolyte losses.
<b>Collaborative</b>	
Administer IV fluids via control device.	Because smaller volumes are administered, close monitoring and regulation are required to prevent fluid overload while correcting fluid balance.
Replace electrolytes, as indicated, by oral route whenever possible.	Replacement solutions formulated for children are often safer and better tolerated when given orally if time and condition allow. Note: Child with mild dehydration not caused by trauma may respond well to oral rehydration starting with 5 to 10 mL by mouth every 15 to 20 minutes and increasing according to tolerance.
Monitor laboratory results, such as hemoglobin/hematocrit (Hgb/Hct), BUN, urine osmolality, and specific gravity.	Indicators of adequacy of hydration and effectiveness of therapeutic interventions.
Arrange with laboratory to combine common tests and draw smallest amount of blood that is necessary to perform required studies.	Excessive or repetitive blood draws may markedly reduce Hgb and Hct levels in pediatric client.

### NURSING DIAGNOSIS: **interrupted Family Processes**

#### May Be Related To

Situational transition and/or crisis  
Shift in health status of a family member  
Change in family finances or social status

#### Possibly Evidenced By

Change in communication pattern; decrease in available emotional support  
Change in participation for problem-solving  
Change in family conflict resolution

#### Desired Outcomes/Evaluation Criteria—Parent/Caregiver Will

#### Family Functioning NOC

Verbalize positive feelings about parenting abilities.  
Be involved in problem-solving solutions for current situation.  
Develop skills to deal with present situation.  
Strengthen parenting skills.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Family Support NIC</b>	
<b>Independent</b>	
Determine existing situation and parental perception of the problems, noting presence of specific factors such as psychiatric or physical illness and disabilities of child or parent.	Identification of the individual factors will aid in focusing interventions and establishing a realistic plan of care.
Identify developmental stage of the family—first child, new infant, school-age or adolescent children, or stepfamily.	These factors affect how family members view current problems and choices of solutions.
Determine cultural and religious influences on parenting and expectations of self and child.	This information is crucial to helping the family identify and develop a treatment plan that meets its specific needs, enhancing likelihood of success.
Assess parenting skill level, considering intellectual, emotional, and physical strengths and limitations.	Identifies areas of need for further education, skill training, and factors that might interfere with ability to assimilate new information.
Note attachment behaviors between parent and child(ren), recognizing cultural background. Encourage parent(s) to hold and spend time with child, particularly newborn or infant.	Lack of eye contact and touching may indicate bonding problems. Failure to bond effectively with newborn is thought to affect subsequent parent-child interaction.
Observe interactions between parent(s) and child(ren).	Identifies relationships, communication pattern/skills, and feelings about one another.
Note presence and effectiveness of extended family support systems.	Provides role models for parent(s) to help them develop own style of parenting. Note: Role models may be negative and/or controlling.
Emphasize positive aspects of situation, maintaining a positive attitude toward parent's capabilities and potential for improving.	Helping parent(s) to feel accepting about self and individual capabilities will promote growth.
Involve all members of the family in learning activities.	Learning new skills is enhanced when everyone is participating and interacting.
Encourage parent(s) to identify positive outlets for meeting own needs, such as going to a movie or out to dinner. Discuss use of home-care and respite services, as appropriate.	Parent often believes it is "selfish" to do things for own self, that children are primary. However, parents are important, children are important, and the family is important. As a rule, when parents take care of themselves, their coping abilities are enhanced and they are better parents. Note: Siblings also require time with parents to attend to their needs and to have positive interactions.
Discuss issues of step-parenting and ways to achieve positive relationships in a blended family.	Blending two families can be a very demanding task, and preconceived ideas can be counterproductive.
<b>Collaborative</b>	
Refer to resources such as books, parenting classes, and support groups.	Providing information and/or role models can help people learn to negotiate and develop skills for parenting and living together.

### NURSING DIAGNOSIS: **risk for ineffective Thermoregulation**

#### Risk Factors May Include

Extremes of age or weight; dehydration  
Fluctuating/extremes of environmental temperature  
Illness, trauma, sepsis; alteration in metabolic rate

#### Desired Outcomes/Evaluation Criteria—Child Will

#### Thermoregulation NOC

Regain or maintain appropriate body temperature for age and size.

#### Parent/Caregiver Will

#### Risk Control NOC

Provide proper environmental controls and safeguards.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Temperature Regulation</b> <small>NIC</small>	
<i>Independent</i>	
Note conditions promoting fevers—Infection, inflammation, hot environment, and dehydration.	Determines choice of interventions.
Measure and monitor child's temperature, using properly functioning thermometer.	Inaccurate measurement can result in inappropriate treatment.
Discuss variables in temperature measurements for age of child and where temperature is measured.	Knowledge of normal ranges for age of child—newborn through adolescent—is critical to knowing when a fever requires treatment. Temperature may be measured orally, rectally, and at the axillary space, with rectal measurement being on average approximately 1 degree higher than oral, and axillary being 1 degree lower than oral. Note: Temperature of 100.4°F (38°C) or greater in newborns and infants needs immediate attention. For toddlers and older children, temperatures up to 104°F (40°C) may be tolerated unless accompanied by other signs, such as poor color, breathing problems, severe lethargy, headache, or stiff neck (Cincinnati Children's Hospital Medical Center [CCHMC], 2010).
Be aware of heat loss related to age and body mass.	Newborn is more vulnerable to heat loss than older child because of body surface area, higher metabolic rate, and sensitivity to environmental conditions.
Observe for seizure activity. Provide safety precautions, as indicated.	Higher fevers may trigger febrile seizures in susceptible children.
Adjust bedclothes, linens, and environment. Apply cool cloth to head and bathe in lukewarm bath.	Limiting linens and use of room fan can help lower body temperature. Note: Use of alcohol sponge bath is contraindicated—can be inhaled or alcohol absorbed through skin (Kids Health for Parents, 2013).
<i>Collaborative</i>	
Administer antipyretics, for example, acetaminophen (Tylenol) 10 to 15 mg/kg every 4 hours or ibuprofen (Motrin) 10 to 15 mg/kg every 6 hours, as indicated. Avoid use of aspirin.	Some degree of fever may be useful for fighting infection; however, excessive levels may have adverse effects and require intervention. Aspirin is believed to be associated with the onset of Reye's syndrome (London, 2007).

## NURSING DIAGNOSIS: risk for ineffective Health Maintenance

### Possibly Evidenced By

Inability to take responsibility for meeting basic health practices  
Insufficient resources/social support; ineffective [family] coping strategies  
Insufficient knowledge about basic health practices

### Desired Outcomes/Evaluation Criteria—Parent/Caregiver Will

#### Health-Seeking Behavior

Identify necessary health maintenance activities.  
Verbalize understanding of factors contributing to current situation.  
Develop plan to meet specific needs.

ACTIONS/INTERVENTIONS	RATIONALE
<b>Health System Guidance</b> <small>NIC</small>	
<i>Independent</i>	
Explore with parents how child's health status is maintained—nutrition (especially if child is over- or underweight), exercise, sleep and rest, immunization status, and social/environmental issues such as child care setting and homelessness.	Identifies strengths; may reveal problems requiring immediate intervention.

ACTIONS/INTERVENTIONS (continued)	RATIONALE (continued)
Discuss mother's health status when pregnant, such as exposure to toxic agents, substance use, and complications of pregnancy or birth.	Helps identify issues, such as fetal alcohol syndrome, that may arise in child's future health status.
Ascertain frequency of routine health exams, including eye and dental care, monitoring by primary care provider, and immunizations. Note availability and use of resources. Problem-solve barriers to meeting healthcare needs.	Identifies areas of child's healthcare that may be lacking and provides parents with information about areas that need to be monitored and care provided to promote optimum health. Note: Financial issues, such as being under- or uninsured, having high insurance copays, or a lack of transportation, may restrict ability to follow through on needed or routine care.
Note desire and level of ability to meet health maintenance needs, as well as self-care ADLs.	Care providers and children who can provide much of their own care may have areas of need, either because of illness or other stressors.
Develop plan with parent or caregiver for child's care.	Allows for incorporating existing strengths or limitations and assistance in adapting and organizing care, as necessary.
Provide time to listen to concerns of parent or caregiver.	Long-term care for chronically ill child or acute care for a child can be very challenging to parent's physical, emotional, and financial resources.
Provide anticipatory guidance for periods of wellness, and identify ways parent can adapt when progressive illness or long-term health problems occur.	Information and support is vital for maintaining and managing effective health practices.
Provide for communication and coordination between the healthcare facility team and community healthcare providers.	Promotes continuity of care and continuation of goals.
Monitor adherence to prescribed medical regimen. Determine causes for deviations.	Additional education or problem-solving may be required for success of therapeutic plan.
Provide information about individual healthcare needs. Identify signs and symptoms requiring further evaluation and follow-up.	Provides for prevention of complications and early intervention in times of illness.
<b>Collaborative</b>	
Provide contact number for case manager following discharge home.	Provides resource to answer questions and assist with navigation through complex healthcare systems.
Make referral as needed for community support services such as homemaker, skilled nursing care, well-baby clinic, and respite care.	Provides for child care and parental support in home setting to enhance coping with therapeutic regimen.
Refer to social services, as indicated.	May need assistance with financial, housing, or legal concerns.
Arrange for palliative or hospice services, if needed.	May be indicated when illness is prolonged or terminal.

**POTENTIAL CONSIDERATIONS** following acute hospitalization (dependent on client's age, physical condition and presence of complications, and family resources).

Refer to primary diagnosis for specific concerns.

- **ineffective Health Management**—perceived seriousness; economic difficulties; complexity of therapeutic regimen; excessive demands made on family; family patterns of healthcare
- **delayed [Growth] and Development**—effects of physical disability; prescribed dependence; environmental or stimulation deficiencies.

# Definitions for NANDA-I Nursing Diagnoses Used in This Text

## A

Activity intolerance: Insufficient physiological or psychological energy to endure or complete required or desired daily activities.

Acute substance withdrawal syndrome: Serious, multifactorial sequelae following abrupt cessation of an addictive compound.

Acute substance withdrawal syndrome, risk for: Susceptible to serious, multifactorial sequelae following abrupt cessation of an addictive compound, which may compromise health.

Adaptive capacity, risk for decreased intracranial: Compromise in intracranial fluid dynamic mechanisms that normally compensate for increases in intracranial volumes, resulted in repeated disproportionate increases in intracranial pressure (ICP) in response to a variety of noxious and non-noxious stimuli.

Airway clearance, ineffective: Inability to clear secretions or obstructions from the respiratory tract to maintain a clear airway.

Anxiety: Vague, uneasy feeling of discomfort or dread accompanied by an autonomic response (the source is often nonspecific or unknown to the individual); a feeling of apprehension caused by anticipation of danger. It is an alerting sign that warns of impending danger and enables the individual to take measures to deal with the threat.

Aspiration, risk for: Susceptible to entry of gastrointestinal secretions, oropharyngeal secretions, solids, or fluids to the tracheobronchial passages, which may compromise health.

Autonomic Dysreflexia, risk for: Susceptible to life-threatening, uninhibited response of the nervous system post-spinal shock, in an individual with spinal cord injury or lesion at the 6<sup>th</sup> thoracic vertebra (T6) or above (has been demonstrated in patients with injuries at the 7<sup>th</sup> thoracic vertebra (T7) and the 8<sup>th</sup> thoracic vertebra (T8), which may compromise health.

## B

Bleeding, risk for: Susceptible to a decrease in blood volume, which may compromise health.

Blood glucose level, risk for unstable: Susceptible to variation in serum levels of glucose from the normal range, which may compromise health.

Blood pressure, risk for unstable: Susceptible to fluctuating forces of blood flowing through arterial vessels, which may compromise health.

Body image, disturbed: Confusion in mental picture of one's physical self.

Bowel incontinence: Involuntary passage of stool.

Breathing pattern, ineffective: Inspiration and/or expiration that does not provide adequate ventilation.

## C

Cardiac output, decreased: Inspiration and/or expiration that does not provide adequate ventilation.

Cardiac output, risk for decreased: Susceptible to inadequate blood pumped by the heart to meet metabolic demands of the body, which may compromise health.

Comfort, impaired: Perceived lack of ease, relief, and transcendence in physical, psychospiritual, environmental, cultural, and/or social dimensions.

Communication, impaired verbal: Decreased, delayed, or absent ability to receive, process, transmit, and/or use a system of symbols.

Confusion, acute: Reversible disturbances of consciousness, attention, cognition, and perception that develop over a short period of time, and which last less than 3 months.

Confusion, chronic: Irreversible, progressive, insidious, and long-term alteration of intellect, behavior and personality, manifested by impairment in cognitive functions (memory, speech, language, decision making, and executive function), and dependency in execution of daily activities.

Constipation: Decrease in normal frequency of defecation accompanied by difficult or incomplete passage of stool and/or passage of excessively hard, dry stool.

Constipation, risk for: Susceptible to a decrease in normal frequency of defecation accompanied by difficult or incomplete passage of stool, which may compromise health.

Coping, compromised family: A usually supportive primary person (family, significant other, or close friend) provides insufficient, ineffective, or compromised support, comfort, assistance, or encouragement that may be needed by the client to manage or master adaptive tasks related to his or her health challenge.

Coping, ineffective: A pattern of invalid appraisal of stressors, with cognitive and/or behavioral efforts, that fails to manage demands related to well-being.

Coping, ineffective community: A pattern of community activities for adaptation and problem-solving that is unsatisfactory for meeting the demands or needs of the community.

Coping, readiness for enhanced community: A pattern of community activities for adaptation and problem-solving for meeting the demands or needs of the community, which can be strengthened.

Coping, readiness for enhanced family: A pattern of management of adaptive tasks by primary person (family, significant other, or close friend) involved with the client's health challenge, which can be strengthened.

Coping, disabled family: Behavior of primary person (family, significant other, or close friend) that disables his or her capacities to effectively address tasks essential to either person's adaptation to the health challenge.

## D

Death anxiety: Vague, uneasy feeling of discomfort or dread generated by perceptions of a real or imagined threat to one's existence.

Decisional conflict: Uncertainty about course of action to be taken when choice among competing actions involves risk, loss, or challenge to values and beliefs.

Denial, ineffective: Conscious or unconscious attempt to disavow the knowledge or meaning of an event to reduce anxiety and/or fear, leading to detriment of health.

Development, risk for delayed: Susceptible to delays of 25% or more in one or more of the areas of social or self-regulatory behavior, or in cognitive, language, gross, or fine motor skills, which may compromise health.

Diarrhea: Passage of loose, unformed stools.

Diversional activity engagement, decreased: Reduced stimulation, interest, or participation in recreational or leisure activities.

Dry eye, risk for: Susceptible to eye discomfort or damage to the cornea and conjunctiva due to reduced quantity or quality of tears to moisten the eye, which may compromise health.

## E

Eating dynamics, ineffective adolescent: Altered eating attitudes and behaviors resulting in over- or under-eating patterns that compromise nutritional health.

Electrolyte imbalance, risk for: Susceptible to changes in serum electrolyte levels, which may compromise health.

Elimination, impaired urinary: Dysfunction in urine elimination.

## F

Family processes, dysfunctional: Family functioning which fails to support the well-being of its members.

Family processes, interrupted: Break in the continuity of family functioning which fails to support the well-being of its members.

Fatigue: An overwhelming sustained sense of exhaustion and decreased capacity for physical and mental work at the usual level.

Fear: Response to perceived threat that is consciously recognized as a danger.

Fluid volume, deficient: Decreased intravascular, interstitial, and/or intracellular fluid. This refers to dehydration, water loss alone without change in sodium.

Fluid volume, excess: Surplus intake and/or retention of fluid.

Fluid volume, risk for deficient: Susceptible to experiencing decreased intravascular, interstitial, and/or intracellular fluid volumes, which may compromise health.

Fluid volume, risk for imbalanced: Susceptible to a decrease, increase, or rapid shift from one to the other of intravascular, interstitial, and/or intracellular fluid volumes, which may compromise health. This refers to body fluid loss, gain, or both.

## G

Gas exchange, impaired: Excess or deficit in oxygenation and/or carbon dioxide elimination at the alveolar-capillary membrane.

Grieving: A normal complex process that includes emotional, physical, spiritual, social, and intellectual responses and behaviors by which individuals, families, and communities incorporate an actual, anticipated, or perceived loss into their daily lives.

## H

Health behavior, risk-prone: Impaired ability to modify lifestyle and/or actions in a manner that improves the level of wellness.

Health maintenance, ineffective: Inability to identify, manage, and/or seek out help to maintain well-being.

Health management, ineffective: Pattern of regulating and integrating into daily living a therapeutic regimen for the treatment of illness and its sequelae that is unsatisfactory for meeting specific health goals.

Home maintenance, risk for impaired: Inability to independently maintain a safe growth-promoting immediate environment.

Hyperthermia: Core body temperature above the normal diurnal range due to failure of thermoregulation.

## I

Incontinence, bowel: Involuntary passage of stool.

Infection, risk for: Susceptible to invasion and multiplication of pathogenic organisms, which may compromise health.

Injury, risk for: Susceptible to physical damage due to environmental conditions interacting with the individual's adaptive and defensive resources, which may compromise health.

Insomnia: A disruption in amount and quality of sleep that impairs functioning.

## K

Knowledge, deficient: Absence of cognitive information related to a specific topic, or its acquisition.

## L

Lifestyle, sedentary: A habit of life that is characterized by a low physical activity level.

Liver function, risk for impaired: Susceptible to a decrease in liver function, which may compromise health.

## M

Memory, impaired: Persistent inability to remember or recall bits of information or skills.

Metabolic imbalance syndrome, risk for: Susceptible to a toxic cluster of biochemical and physiological factors associated with the development of cardiovascular disease arising from obesity and type 2 diabetes, which may compromise health.

Mobility, impaired physical: Limitation in independent, purposeful movement of the body or of one or more extremities.

Mucous membrane integrity, impaired oral: Injury to the lips, soft tissue, buccal cavity, and/or oropharynx.

## N

Nausea: A subjective phenomenon of an unpleasant feeling in the back of the throat and stomach, which may or may not result in vomiting.

Neurovascular dysfunction, risk for peripheral: Susceptible to disruption in the circulation, sensation, and motion of an extremity, which may compromise health.

Nutrition, less than body requirements, imbalanced: Intake of nutrients insufficient to meet metabolic needs.

## O

Obesity: A condition in which an individual accumulates excessive fat for age and gender that exceeds overweight.

Overweight: A condition in which an individual accumulates excessive fat for age and gender.

Overweight, risk for: Susceptible to excessive fat accumulation for age and gender, which may compromise health.

## P

Pain, acute: Unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage (International Association for the Study of Pain); sudden or slow onset of any intensity from mild to severe with an anticipated or predictable end, and with a duration of less than 3 months.

Pain, chronic: Unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage (International Association for the Study of Pain); sudden or slow onset of any intensity from mild to severe, constant or recurring without an anticipated or predictable end, and with a duration of greater than 3 months.

Parenting, impaired: Inability of primary caregiver to create, maintain, or regain an environment that promotes the optimum growth and development of the child.

Perioperative positioning injury, risk for: Susceptible to inadvertent anatomical and physical changes as a result of posture or positioning equipment used during an invasive/surgical procedure, which may compromise health.

Poisoning, risk for: Susceptible to accidental exposure to, or ingestion of, drugs or dangerous products in sufficient doses, which may compromise health.

Post-trauma syndrome, risk for: Susceptible to sustained maladaptive response to a traumatic, overwhelming event, which may compromise health.

Powerlessness: The lived experience of lack of control over a situation, including a perception that one's actions do not significantly affect an outcome.

## R

Religiosity, risk for impaired: Susceptible to an impaired ability to exercise reliance on religious beliefs and/or participate in rituals of a particular faith tradition, which may compromise health.

Relocation stress syndrome, risk for: Susceptible to physiological disturbance following transfer from one environment to another, which may compromise health.

Retention, urinary: Inability to empty bladder completely.

Role performance, ineffective: A pattern of behavior and self-expression that does not match the environmental context, norms, and expectations.

Role strain, risk for caregiver: Susceptible to difficulty in fulfilling care responsibilities, expectations, and/or behaviors for family or significant others, which may compromise health.

## S

Self-care deficit [specify]: Inability to eat independently, independently complete cleansing activities, put on or remove clothing, perform tasks associated with bowel and bladder elimination.

Self-care, readiness for enhanced: A pattern of performing activities for oneself to meet health-related goals, which can be strengthened.

Self-esteem, chronic low: Negative evaluations and/or feelings about one's own capabilities, lasting at least 3 months.

Self-esteem, situational low: Development of a negative perception of self-worth in response to a current situation.

Sensory perception, disturbed (specify): Change in the amount or patterning of incoming stimuli accompanied by a diminished, exaggerated, distorted, or impaired response to such stimuli.

Sexual dysfunction: A state in which an individual experiences a change in sexual function during the sexual response phases of desire, arousal, and/or orgasm, which is viewed as unsatisfying, unrewarding, or inadequate.

Shock, risk for: Susceptible to an inadequate blood flow to the body's tissues that may lead to life-threatening cellular dysfunction, which may compromise health.

Skin integrity, impaired: Altered epidermis and/or dermis.

Skin integrity, risk for impaired: Susceptible to alteration in epidermis and/or dermis, which may compromise health.

Sleep deprivation: Prolonged periods of time without sustained natural, periodic suspension of relative consciousness that provides rest.

Sleep pattern, disturbed: Time-limited awakenings due to external factors.

Social interaction, impaired: Insufficient or excessive quantity or ineffective quality of social exchange.

Social isolation: Aloneness experienced by the individual and perceived as imposed by others and as a negative or threatening state.

Spiritual distress: A state of suffering related to the impaired ability to experience meaning in life through connections with self, others, the world, or a superior being.

Suffocation, risk for: Susceptible to inadequate air availability for inhalation, which may compromise health.

Surgical site infection, risk for: Susceptible to invasion of pathogenic organism at surgical site, which may compromise health.

Swallowing, impaired: Abnormal functioning of the swallowing mechanism associated with deficits in oral, pharyngeal, or esophageal structure or function.

## T

Thermoregulation, risk for ineffective: Susceptible to temperature fluctuation between hypothermia and hyperthermia, which may compromise health.

Thromboembolism, risk for venous: Susceptible to the development of a blood clot in a deep vein, commonly in the thigh, calf, or upper extremity, which can break off and lodge in another vessel, which may compromise health.

Tissue integrity, impaired: Damage to the mucous membrane, cornea, integumentary system, muscular fascia, muscle, tendon, bone, cartilage, joint capsule, and/or ligament.

Tissue perfusion, ineffective peripheral: Decrease in blood circulation to the periphery, which may compromise health.

Tissue perfusion, risk for decreased cardiac: Susceptible to a decrease in cardiac circulation, which may compromise health.

Tissue perfusion, risk for ineffective cerebral: Susceptible to a decrease in cerebral tissue circulation, which may compromise health.

Tissue perfusion, risk for ineffective peripheral: Susceptible to a decrease in blood circulation to the periphery, which may compromise health.

Trauma, risk for physical: Susceptible to physical injury of sudden onset and severity which require immediate attention.

**U**

Unilateral neglect: Impairment in sensory and motor response, mental representation, and spatial attention of the body, and the corresponding environment, characterized by inattention to one side and overattention to the opposite side. Left-side neglect is more severe and persistent than right-side neglect.

**V**

Ventilation, impaired spontaneous: Inability to initiate and/or maintain independent breathing that is adequate to support life.

Ventilatory weaning response, dysfunctional: Inability to adjust to lowered levels of mechanical ventilator support that interrupts and prolongs the weaning process.

Violence, risk for other-directed: Susceptible to behaviors in which an individual demonstrates that he or she can be physically, emotionally, and/or sexually harmful to others.

Violence, risk for self-directed: Susceptible to behaviors in which an individual demonstrates that he or she can be physically, emotionally, and/or sexually harmful to self.

# Index of Nursing Diagnoses

Activity intolerance: anemias—iron deficiency, anemia of chronic disease, pernicious, aplastic, hemolytic and, 547; angina, chronic/stable and risk for, 69; chronic heart failure and, 46; hypertension: severe and, 32; myocardial infarction and risk for, 82; pediatric considerations and, 998; renal failure: chronic kidney disease/end-stage renal disease and risk for, 616

Acute substance withdrawal syndrome: substance use disorders and risk for, 934

Airway clearance, ineffective: burns: thermal, chemical, electrical (acute/convalescent phases) and risk for, 746; chronic obstructive pulmonary disease and, 137; lung cancer: postoperative care and, 165; pneumonia and, 151; pulmonary tuberculosis and, 210; respiratory failure/ventilatory assistance and, 195; seizure disorders and risk for, 222

Anxiety: benign prostatic hyperplasia and, 692; cancer and, 950; dementias—Alzheimer's type/vascular dementia/Lewy body disease/frontotemporal dementia and, 862; disaster considerations and, 986; hyperthyroidism/thyrotoxicosis/thyroid storm and, 478; inflammatory bowel disease and, 363; lung cancer: postoperative care and, 167; mastectomy and, 679; myocardial infarction and, 82; pediatric considerations and, 997; peritonitis and, 398; renal dialysis and, 630; respiratory failure/ventilatory assistance and, 197; surgical interventions and, 878; upper gastrointestinal bleeding and, 349

Anxiety, death: acquired immunodeficiency syndrome and, 819; palliative/end-of-life care/hospice and, 975

Aspiration, risk for: total nutritional support: parenteral/enteral feeding and, 536

Autonomic dysreflexia, risk for: spinal cord injury (acute care/rehabilitative phase) and, 309

Bleeding, risk for: acquired immunodeficiency syndrome and, 810; aortic aneurysms and, 116; cirrhosis of liver and, 505; hepatitis and, 490; prostatectomy and, 697; renal failure: chronic kidney disease/end-stage renal disease and risk for, 617; total joint replacement and, 733

Blood glucose level, unstable: diabetes mellitus/diabetic ketoacidosis and, 461; pancreatitis and risk for, 521

Body image, disturbed: cirrhosis of liver and, 509; eating disorders: anorexia nervosa/bulimia nervosa and, 424; fecal diversions and, 370; obesity and risk for, 438; renal dialysis and, 632; urostomy: postoperative care and, 649

Body temperature. *See* Hyperthermia; Hypothermia; Thermoregulation

Bowel incontinence: dementias—Alzheimer's type/vascular dementia/Lewy body disease/frontotemporal dementia and, 867; multiple sclerosis and risk for, 322; spinal cord injury (acute care/rehabilitative phase) and, 302

Breathing pattern, ineffective: acquired immunodeficiency syndrome and risk for, 808; alcohol, acute withdrawal and risk for, 927; bariatric surgery and, 445; cardiac surgery: postoperative care and risk for, 106; cholecystectomy and, 408; cirrhosis of liver and risk for, 504; coronary artery bypass graft and risk for, 106; craniocerebral trauma and risk for, 237; peritoneal dialysis and risk for, 640; pneumothorax/

hemotorax, 173; respiratory failure/ventilatory assistance, 192; spinal cord injury (acute care/rehabilitative phase) and risk for, 292; spinal surgery and risk for, 281; surgical interventions and, 886

Cardiac output, decreased: acute coronary syndrome and risk for, 61; acute kidney injury (acute renal failure) and, 603; alcohol, acute withdrawal and risk for, 928; cardiac surgery: postoperative care and risk for, 102; chronic heart failure and, 43; coronary artery bypass graft and risk for, 102; dysrhythmias and risk for, 90; hypertension: severe and risk for, 30; hyperthyroidism/thyrotoxicosis/thyroid storm and risk for, 475; myocardial infarction and risk for, 79; renal failure: chronic kidney disease/end-stage renal disease and risk for, 614

Caregiver role strain, risk for: dementias—Alzheimer's type/vascular dementia/Lewy body disease/frontotemporal dementia and, 871; multiple sclerosis and, 327; palliative/end-of-life care/hospice and, 979

Comfort, impaired: brain infections: meningitis/encephalitis and, 273

Communication, impaired: cerebrovascular accident and, 257

Communication, impaired verbal: extended/long-term care and, 905;

respiratory failure/ventilatory assistance and, 196

Confusion, acute: acquired immunodeficiency syndrome and risk for, 817; cirrhosis of liver and risk for, 507; craniocerebral trauma and risk for, 238; renal dialysis and risk for, 630; renal failure: chronic kidney disease/end-stage renal disease and risk for, 618; sepsis/septic shock and risk for, 782

Confusion, chronic: acquired immunodeficiency syndrome and risk for, 817; dementias—Alzheimer's type/vascular dementia/Lewy body disease/frontotemporal dementia and, 858; Parkinson's disease and risk for, 338

Constipation: spinal cord injury (acute care/rehabilitative phase) and, 302

Constipation, risk for: cancer and, 965; extended/long-term care and, 912; fecal diversions and, 377; hysterectomy and, 669; multiple sclerosis and, 322; renal dialysis and, 629; total joint replacement and, 737

Coping, compromised family: dementias—Alzheimer's type/vascular dementia/Lewy body disease/frontotemporal dementia and, 869; extended/long-term care and, 903; multiple sclerosis and risk for, 326; palliative/end-of-life care/hospice and, 977; psychosocial aspects of care and, 839

Coping, ineffective: cerebrovascular accident and, 261; diabetes mellitus and, 466; hypertension: severe and, 34; inflammatory bowel disease and, 365; multiple sclerosis and risk for, 323; psychosocial aspects of care and, 837; substance use disorders and, 936

Coping, ineffective community: disaster considerations and, 991

Coping, readiness for enhanced community: disaster considerations and, 992

Coping, readiness for enhanced family: eating disorders: anorexia nervosa/bulimia nervosa and, 427; psychosocial aspects of care and, 840

Death anxiety: acquired immunodeficiency syndrome and, 819;

palliative/end-of-life care/hospice and, 975

Decisional conflict: psychosocial aspects of care and, 838

- Denial, ineffective: substance use disorders and, 932
- Development, risk for delayed: pediatric considerations and, 999
- Diarrhea: bariatric surgery and, 451; cancer and risk for, 965; extended/long-term care and risk for, 912; fecal diversions and risk for, 377; inflammatory bowel disease and, 359
- Dry eye, risk for: hyperthyroidism (Graves' disease, thyrotoxicosis) and, 480
- Eating dynamics, ineffective child/adolescent: eating disorders: anorexia nervosa/bulimia nervosa and, 420
- Electrolyte imbalance: renal failure: chronic kidney disease/end-stage renal disease and risk for, 613
- Family processes, dysfunctional: substance use disorders and, 941
- Family processes, interrupted: cancer and risk for, 967; craniocerebral trauma and, 244
- Fatigue: acquired immunodeficiency syndrome and, 816; cancer and, 960; HIV-positive client and, 790; hyperthyroidism/thyrotoxicosis/thyroid storm and, 477; leukemias and, 578; multiple sclerosis and, 315; palliative/end-of-life care/hospice and, 974
- Fear: cancer and, 950; pediatric considerations, 997
- Fluid volume, deficient: diabetes mellitus and, 459; inflammatory bowel disease and, 361; pancreatitis and, 517; upper gastrointestinal bleeding and, 344
- Fluid volume, excess: chronic heart failure, 47; renal/urinary tract disorders and, 601
- Fluid volume, risk for deficient: acquired immunodeficiency syndrome and, 807; acute kidney injury (acute renal failure) and, 604; appendectomy and, 386; bariatric surgery and, 447; benign prostatic hyperplasia and, 691; burns: thermal, chemical, electrical (acute/convalescent phases) and, 747; cancer and, 959; cholecystectomy and, 409; cholelithiasis and, 404; eating disorders: anorexia nervosa/bulimia nervosa and, 423; fecal diversions and, 375; hemodialysis and, 643; hepatitis and, 490; leukemias and, 575; peritoneal dialysis and, 636; pneumonia and, 157; renal/urinary tract disorders and, 604; sepsis/septic shock and, 781; sickle-cell crisis and, 564; surgical interventions and, 889; urinary stones (calculi) and, 663
- Fluid volume, risk for excess: cirrhosis of liver and, 500; hemodialysis and, 644; peritoneal dialysis and, 635
- Fluid volume, risk for imbalanced: acute lung injury, 183; pediatric considerations and, 1003; total nutritional support: parenteral/enteral feeding and, 537
- Gas exchange, impaired: acute lung injury and, 181; chronic heart failure and risk for, 49; chronic obstructive pulmonary disease and, 140; fractures and risk for, 711; lung cancer: postoperative care and, 163; lymphomas and risk for, 587; pancreatitis and risk for, 523; pneumonia and, 153; pulmonary tuberculosis and risk for, 211; sepsis/septic shock and risk for, 783; sickle-cell crisis and, 559; venous thromboembolism and, 128
- Glucose level, unstable blood: diabetes mellitus/diabetic ketoacidosis and, 461; pancreatitis and risk for, 521
- Grieving: amputation and, 726; cancer and, 952; dementias—Alzheimer's type/vascular dementia/Lewy body disease/frontotemporal dementia and, 863; extended/long-term care and, 900; hysterectomy and, 672; palliative/end-of-life care/hospice and, 975; psychosocial aspects of care and, 845; spinal cord injury (acute care/rehabilitative phase) and, 299
- Growth and development, delayed: pediatric considerations and risk for, 999
- Health behavior, risk-prone: HIV-positive client and, 788
- Health maintenance, ineffective: dementias—Alzheimer's type/vascular dementia/Lewy body disease/frontotemporal dementia and, 870; pediatric considerations and risk for, 1006
- Health management, ineffective: acquired immunodeficiency syndrome and, 822; angina: chronic/stable and, 70; aortic aneurysms and, 119; chronic heart failure and, 51; chronic obstructive pulmonary disease and, 143; cirrhosis of liver and, 509; diabetes mellitus and, 467; dysrhythmias and, 96; eating disorders: anorexia nervosa/bulimia nervosa and, 429; HIV-positive client and, 798; hypertension: severe and, 35; inflammatory bowel disease and, 366; obesity and, 441; pancreatitis and, 523; psychosocial aspects of care and, 848; pulmonary tuberculosis and risk for, 214; renal dialysis and risk for, 633; renal failure: chronic kidney disease/end-stage renal disease and, 620; rheumatoid arthritis and risk for, 832; sickle-cell crisis and, 566; wounds/wound care and risk for, 770
- Health management, readiness for enhanced: cancer and, 967; extended/long-term care and, 917; multiple sclerosis and, 328; seizure disorders and, 224; surgical interventions and, 895
- Hyperthermia: sepsis/septic shock and, 778; surgical interventions and risk for, 885
- Hypothermia: surgical interventions and risk for, 885
- Incontinence, bowel: dementias—Alzheimer's type/vascular dementia/Lewy body disease/frontotemporal dementia and, 867; multiple sclerosis and risk for: constipation, 322; spinal cord injury (acute care/rehabilitative phase) and, 302
- Infection, risk for: acquired immunodeficiency syndrome and, 805; acute kidney injury (acute renal failure) and, 605; amputation and, 724; anemias—iron deficiency, anemia of chronic disease, pernicious, aplastic, hemolytic and, 550; appendectomy and, 385; bariatric surgery and, 450; burns: thermal, chemical, electrical (acute/convalescent phases) and, 751; cancer and, 961; cirrhosis of liver and, 502; diabetes mellitus and, 464; disaster considerations and, 985; fecal diversions and, 374; fractures and, 715; hepatitis and, 492; leukemias and, 574; pancreatitis and, 522; peritoneal dialysis and, 639; peritonitis and, 392; pneumonia and, 154; prostatectomy and, 698; pulmonary tuberculosis and, 208; renal/urinary tract disorders and, 605; respiratory failure/ventilatory assistance and, 199; sepsis/septic shock and, 776; sickle-cell crisis and, 566; spinal surgery and, 283; surgical interventions and, 883; total joint replacement and, 734; total nutritional support: parenteral/enteral feeding and, 534; urostomy: postoperative care and, 651; wounds/wound care and, 769
- Injury, risk for: dementias—Alzheimer's type/vascular dementia/Lewy body disease/frontotemporal dementia and, 856; disaster considerations and, 983; fractures and, 706; hemodialysis and, 642; perioperative positioning, 880; seizure disorders and, 220; spinal surgery and, 280; surgical interventions and, 881; total nutritional support: parenteral/enteral feeding and, 535
- Insomnia. *See* Sleep deprivation; Sleep, disturbed pattern of
- Intracranial adaptive capacity, risk for decreased: brain infections and, 272; craniocerebral trauma and, 233
- Knowledge, deficient: acute coronary syndrome and, 63; acute kidney injury (acute renal failure) and, 606; amputation and, 728; anemias—iron deficiency, anemia of chronic disease, pernicious, aplastic, hemolytic and, 551; appendectomy and, 388; bariatric surgery and, 452; benign prostatic hyperplasia and, 693; brain infections and, 275; burns: thermal, chemical, electrical (acute/convalescent phases) and, 760; cardiac surgery: postoperative care and, 108; cerebrovascular accident and, 265; cholecystectomy and, 411; cholelithiasis and, 406; craniocerebral trauma and, 245; fecal diversions and, 380; fractures and, 716; HIV-positive client and, 793; hyperthyroidism/thyrotoxicosis/thyroid storm and, 481; hysterectomy and, 673; leukemias and, 580; lung cancer: postoperative care and, 167; lymphomas and, 592; mastectomy and, 684; myocardial infarction and, 83; peritonitis and, 398; pneumonia and, 157; pneumothorax/hemothorax and, 176; prostatectomy and, 700; renal/urinary tract disorders and, 606; respiratory failure/ventilatory assistance and, 203; sepsis/septic shock and, 784; spinal cord injury (acute care/rehabilitative phase) and, 306; spinal surgery and, 286; substance use disorders and, 944; surgical interventions and, 877; total joint replacement and, 738; total nutritional support: parenteral/enteral feeding and, 538; upper gastrointestinal bleeding and, 351; urinary stones (calculi) and, 664; urostomy: postoperative care and, 654; venous thromboembolism and, 130
- Knowledge, readiness for enhanced: pneumothorax/hemothorax and, 176; surgical interventions and, 877
- Lifestyle, sedentary: obesity and, 437
- Liver function, impaired: hepatitis and, 486

- Memory, impaired: extended/long-term care, 901
- Mobility, impaired physical: amputation and, 725; burns: thermal, chemical, electrical (acute/convalescent phases) and, 756; cerebrovascular accident and, 255; extended/long-term care and, 914; fractures and, 712; mastectomy and risk for, 683; Parkinson's disease and, 333; rheumatoid arthritis and, 829; sickle-cell crisis, 564; spinal cord injury (acute care/rehabilitative phase) and, 295; spinal surgery and, 283; total joint replacement and, 736
- Nausea: lymphomas and, 590
- Neglect, unilateral: cerebrovascular accident and, 264
- Nutrition: less than body requirements, imbalanced: acquired immunodeficiency syndrome and, 811; anemias—iron deficiency, anemia of chronic disease, pernicious, aplastic, hemolytic and, 549; bariatric surgery and risk for, 448; burns: thermal, chemical, electrical (acute/convalescent phases) and, 755; cancer, 957; cancer and risk for, 957; chronic obstructive pulmonary disease and, 142; cirrhosis of liver and, 498; craniocerebral trauma and, 241; dementias—Alzheimer's type/vascular dementia/Lewy body disease/frontotemporal dementia and risk for, 866; eating disorders: anorexia nervosa/bulimia nervosa and, 420; extended/long-term care and, 907; fecal diversions and, 376; hepatitis and, 489; HIV-positive client and, 791; hyperthyroidism/thyrototoxicosis/thyroid storm and risk for, 478; inflammatory bowel disease and, 361; pancreatitis and, 519; pediatric considerations and risk for, 1001; pulmonary tuberculosis and, 212; renal dialysis and, 625; respiratory failure/ventilatory assistance and, 198; substance use disorders and, 938; total nutritional support: parenteral/enteral feeding and, 530; wounds/wound care and, 769
- Obesity: as nursing diagnosis related to obesity, 343
- Oral mucous membrane, impaired: acquired immunodeficiency syndrome and, 815; cancer and, 962; renal failure: chronic kidney disease/end-stage renal disease and risk for, 620; respiratory failure/ventilatory assistance and, 198
- Overweight: hypertension: severe and, 33
- Pain, acute: acute coronary syndrome and, 58; amputation and, 721; angina: chronic/stable and, 67; aortic aneurysms and, 117; appendectomy and, 387; benign prostatic hyperplasia and, 691; burns: thermal, chemical, electrical (acute/convalescent phases) and, 749; cancer and, 954; cardiac surgery: postoperative care and, 104; cholecystitis with cholelithiasis and, 403; coronary artery bypass graft and, 104; fecal diversions and, 371; fractures and, 707; hypertension: severe and, 32; leukemias and, 577; lung cancer: postoperative care and, 166; lymphomas and, 588; mastectomy and, 681; myocardial infarction and, 77; palliative/end-of-life care/hospice and, 972; pancreatitis and, 516; pediatric considerations and, 996; peritoneal dialysis and, 638; peritonitis and, 396; pneumonia and, 156; prostatectomy and, 699; rheumatoid arthritis and, 827; sickle-cell crisis and, 560; spinal cord injury (acute care/rehabilitative phase) and, 298; spinal surgery and, 281; surgical interventions and, 890; total joint replacement and, 731; upper gastrointestinal bleeding and, 350; urinary stones (calculi) and, 660; urostomy: postoperative care and, 650; venous thromboembolism and, 127; wounds/wound care and, 767
- Pain, chronic: cancer and, 954; chronic heart failure and, 50; extended/long-term care and, 915; lymphomas and, 588; palliative/end-of-life care/hospice and, 972; pediatric considerations and, 996; rheumatoid arthritis and, 827; sickle-cell crisis and, 560; venous thromboembolism and, 127; wounds/wound care and, 767
- Panic, severe: disaster considerations and, 986
- Perioperative positioning injury, risk for: surgical interventions and, 880
- Peripheral neurovascular dysfunction, risk for: burns: thermal, chemical, electrical (acute/convalescent phases) and, 754; fractures and, 709; spinal surgery and, 279; total joint replacement and, 735
- Poisoning, risk for: (digoxin toxicity) dysrhythmias and, 94; (drug toxicity) extended/long-term care and, 904; pediatric considerations, 1002
- Post-trauma syndrome, risk for: burns: thermal, chemical, electrical (acute/convalescent phases) and, 759; disaster considerations and, 990
- Powerlessness: multiple sclerosis and risk for, 324; substance use disorders and, 937
- Pressure ulcer, risk for: fractures and, 714; spinal cord injury (acute care/rehabilitative phase) and, 305
- Religiosity, impaired: psychosocial aspects of care and risk for, 847
- Relocation stress syndrome: dementias—Alzheimer's type/vascular dementia/Lewy body disease/frontotemporal dementia and, 872; extended/long-term care and, 898
- Role performance, ineffective: rheumatoid arthritis and risk for, 830
- Self-care deficit: cerebrovascular accident and, 260; dementias—Alzheimer's type/vascular dementia/Lewy body disease/frontotemporal dementia and, 865; extended/long-term care and, 909; multiple sclerosis and, 318; renal dialysis and, 628; rheumatoid arthritis and, 832
- Self-esteem, chronic low: eating disorders: anorexia nervosa/bulimia nervosa and, 425; mastectomy and risk for, 682; multiple sclerosis and risk for, 324; seizure disorders and risk for, 223; spinal cord injury (acute care/rehabilitative phase) and risk for, 301; substance use disorders and risk for, 939
- Self-esteem, situational low, risk for: cancer and, 953; hepatitis and, 491; psychosocial aspects of care and, 843; seizure disorders and, 223
- Sensory perception, disturbed: cerebrovascular accident and, 258; craniocerebral trauma and, 239; dementias—Alzheimer's type/vascular dementia/Lewy body disease/frontotemporal dementia and, 861; diabetes mellitus and, 465; spinal cord injury (acute care/rehabilitative phase) and, 297; surgical interventions and, 887
- Sexual dysfunction: cancer and risk for, 966; dementias—Alzheimer's type/vascular dementia/Lewy body disease/frontotemporal dementia and risk for, 868; extended/long-term care and risk for, 916; fecal diversions and risk for, 378; hysterectomy and, 671; lymphomas and, 591; prostatectomy and risk for, 700; substance use disorders and, 943; urostomy: postoperative care and risk for, 653
- Shock, risk for: peritonitis and, 395; sepsis and, 779; upper gastrointestinal bleeding and, 348
- Skin integrity, impaired: bariatric surgery, 449; burns: thermal, chemical, electrical (acute/convalescent phases) and, 757; cardiac surgery: postoperative care, 107; cholecystectomy and, 410; wounds/wound care and, 765
- Skin integrity, risk for impaired: acquired immunodeficiency syndrome and, 814; cancer and, 964; chronic heart failure and, 50; cirrhosis of liver and, 503; eating disorders: anorexia nervosa/bulimia nervosa and, 428; extended/long-term care and, 910; fecal diversions and, 372; fractures and, 714; renal dialysis and, 627; renal failure: chronic kidney disease/end-stage renal disease and, 619; sickle-cell crisis and, 565; urostomy: postoperative care and, 647
- Sleep deprivation: dementias—Alzheimer's type/vascular dementia/Lewy body disease/frontotemporal dementia and, 864
- Sleep, disturbed pattern of: dementias—Alzheimer's type/vascular dementia/Lewy body disease/frontotemporal dementia and, 864; extended/long-term care and, 906; fecal diversions and, 378
- Social isolation: acquired immunodeficiency syndrome and, 820; HIV-positive client and risk for, 797; obesity and, 440
- Spiritual distress, risk for: disaster considerations and, 989; palliative/end-of-life care/hospice and, 978
- Substance withdrawal syndrome, acute: substance use disorders and risk for, 934
- Suffocation: pediatric considerations and risk for, 1002
- Swallowing, impaired: cerebrovascular accident and risk for, 262; Parkinson's disease and, 336
- Thermoregulation, ineffective: pediatric considerations and risk for, 1005
- Tissue integrity, impaired: bariatric surgery, 449; cardiac surgery: postoperative care, 107; mastectomy and, 680; presurgical interventions and, 892; spinal cord injury (acute care/rehabilitative phase) and risk for, 305; wounds/wound care and, 765
- Tissue perfusion, ineffective peripheral: amputation and risk for, 723; venous thromboembolism and, 125
- Tissue perfusion, inefficient cerebral: cerebrovascular accident and, 252

- Tissue perfusion, risk for decreased cardiac: acute coronary syndrome and, 60; myocardial infarction and, 78
- Tissue perfusion, risk for ineffective: aortic aneurysms and, 115; bariatric surgery and, 447; hysterectomy and, 670; sickle-cell crisis and, 562; surgical interventions and, 894
- Trauma, risk for physical: craniocerebral trauma and, 243; disaster considerations, 983; pediatric considerations, 1002; peritoneal dialysis and, 637; spinal cord injury (acute care/rehabilitative phase) and, 294
- Unilateral neglect: cerebrovascular accident and, 264
- Urinary elimination, impaired: extended/long-term care and risk for, 911; multiple sclerosis and, 320; prostatectomy and, 696; spinal cord injury (acute care/rehabilitative phase) and, 303; urinary stones (calculi) and, 661; urostomy: postoperative care, 652
- Urinary retention: acute/chronic: benign prostatic hyperplasia, 689; hysterectomy and risk for, 668; spinal surgery and risk for, 285
- Ventilation, impaired spontaneous: respiratory failure/ventilatory assistance and, 192
- Ventilatory weaning response, dysfunctional: respiratory failure/ventilatory assistance and risk for, 201
- Violence, self-/other-directed: psychosocial aspects of care and risk for, 849
- Walking, impaired: Parkinson's disease and, 333

## CHAPTER 2

### Books

- Braverman, AC, et al: Diseases of the aorta. In Bonow, RO, et al (eds): Braunwald's heart disease: A textbook of cardiovascular medicine, ed 9, vol 2, pp. 1309–1337. Saunders, Philadelphia, 2012.

Green, G, and Kron, I: Aortic dissection. In Kron, L, and Edmonds, L (eds.): Cardiac surgery in the adult, pp. 1095–1122. McGraw-Hill, New York, 2003.

Gullanick, M, and Myers, JL: Nursing care plans: Diagnoses, interventions, and outcomes, ed 8. Elsevier Mosby, Philadelphia, 2014.

LeFever Kee, J: Laboratory and diagnostic tests with nursing implications, ed 8. Pearson Prentice Hall, Upper Saddle River, NJ, 2009.

McCance, KL, and Heuther, SE: Pathophysiology: The biologic basis for disease in adults and children, ed 6. Elsevier, New York, 2009.

Smeltzer, S, Bare, BG, Hinkle, JL, et al: Brunner and Suddarth's textbook of medical-surgical nursing, ed 11. Lippincott, Williams & Wilkins, Philadelphia, 2010.

Vallerand, AH, Sanoski, CA, and Deglin, JH: Davis's drug guide for nurses, ed 15. F. A. Davis, Philadelphia, 2017.

Van Leeuwen, AM, and Bladh, ML: Davis's comprehensive handbook of laboratory and diagnostic tests with nursing implications, ed 6. F. A. Davis, Philadelphia, 2015.

### Articles

Aggarwal, S, Qamar A, Sharma V, et al: Abdominal aortic aneurysm: a comprehensive review. *Exp Clin Cardiol* 16(1):11–15, 2011.

American Geriatrics Society: 2015 Updated Beers criteria for potentially inappropriate medication use in older adults. *J Am Geriatr Soc* 63(11):2227–2246, 2015.

Antman, EM, Cohen, M, Bernink, PJ, et al: The TIMI risk score for unstable angina/non-ST elevation MI: A method for prognostication and therapeutic decision making. *JAMA* 284(7):835–842, 2000.

Bellchambers, J, Deane, S, and Pottle, A: Diagnosis and management of angina for the cardiac nurse. *Br J Cardiac Nursing* 11(7), 324–327, 2016.

Bellomo, T, and Cichminski, L: Heart matters: Aortic dissection: Every second counts. *Nursing Made Incredibly Easy!* 11(4):10–13, 2013.

Benjamin, EJ, Blaha, MJ, Chiuve, SE, et al: Heart disease and stroke statistics—2017 update: A report from the American Heart Association, Chapter 20. *Circulation* 2017;135:e360–e377.

Brady, AR, Thompson, SG, Fowkes, FG, et al: Abdominal aortic aneurysm expansion: Risk factors and time intervals for surveillance. *Circulation* 110:16–21, 2004.

Braun, LT: Cardiovascular disease: Strategies for risk assessment and modification. *J Cardiovas Nurs* 21(6)(Suppl):S20–S42, 2006.

Braun, LT, and Davidson, MH: Cholesterol-lowering drugs bring benefits to high-risk populations even when LDL is normal. *J Cardiovas Nurs* 18(1):44–49, 2003.

Bronstein AC, Spyker DA, Cantilena LR, et al: 2008 Annual Report of the American Association of Poison Control Centers' National Poison Data System (NPDS): 26th annual report. *Clin Toxicol* 47(10):911–1044, 2009.

## CHAPTER 3

### Books

- Agency for Healthcare Research and Quality (AHRQ): Early mobility guide for reducing ventilator-associated events in mechanically ventilated patients. AHRQ Publication No. 16(17)-0018-4-EF. January 2017.
- Carroll, P: Evidence-based care of patients with chest tubes. Lecture at 2013 American Association of Critical-Care Nurses (AACN) National Teaching Institute. May 20–23, 2013, Boston, MA.
- Clochesy, JM: Interventions for critically ill clients with respiratory problems. In Ignatavicius, DD, and Workman, ML (eds): Medical-surgical nursing: Critical thinking for collaborative care, ed 5. Elsevier Saunders, St. Louis, MO, 2006.
- Doenges, ME, Moorhouse, MF, Murr, AC: ND: Risk for disuse syndrome. In Nurse's pocket guide: Diagnoses, prioritized interventions, and rationales, ed 14. F. A. Davis, Philadelphia, 2016.
- Gould, B, and Dyer, R: Pathophysiology for health professionals, ed 6. Saunders, Philadelphia, 2014.
- Gulanik, M, and Myers, JL: Nursing care plans: Diagnoses, interventions, and outcomes, ed 8. Elsevier Mosby, Philadelphia, 2014.
- Kee, JL, Paulanka, BJ, and Polek, C: Handbook of fluid, electrolyte, and acid-base imbalances, ed 3. Delmar, Clifton Park, NY, 2010.
- Pickett, J: Closed chest drainage system Procedure #24. In Lynn-McHale Wiengand, D (ed): AACN procedure manual for critical care, ed 6, pp. 184–203. Elsevier Saunders, St. Louis, MO, 2011.
- Pooler, C: Disorders of ventilation and gas exchange. In Porth, CM, and Matlin, G (eds): Pathophysiology: Concepts of altered health states, pp. 701–738. Wolters Kluwer, Philadelphia, 2009.
- Schumann, L: Respiratory function and alterations in gas exchange. In Copstead, LEC, and Banasik, JL (eds): Pathophysiology, ed 3. Elsevier Saunders, St. Louis, MO, 2005.
- Springhouse, PA (ed): Pathophysiology made incredibly easy!, ed 3. Lippincott, Williams & Wilkins, Philadelphia, 2006.
- Vallerand, AH, Sanoski, CA, and Deglan, JH: Davis's drug guide for nurses, ed 15. F. A. Davis, Philadelphia, 2010.

## CHAPTER 14

### Books

- American Psychiatric Association: Diagnosis and statistical manual of mental disorders, ed 5. American Psychiatric Assoc., Arlington, VA, 2013.
- Association of PeriOperative Registered Nurses (AORN): Perioperative standards and recommended practices, 2011 ed. AORN, Inc., Denver, CO, 2011, p 367.
- Atkinson, S: Geriatric pharmacology: The principles of practice and clinical recommendations, ed 2. PESI Publishing and Media, Eau Claire, WI, 2016.
- Bodtke, S, and Ligon, K: Hospice and palliative medicine handbook: A clinical guide. CreateSpace Independent Publishing Platform, San Bernardino, CA, 2016.
- Doenges, M, Townsend, M, and Moorhouse, M: Psychiatric nursing care plans, ed 3. F. A. Davis, Philadelphia, 1998.
- Doenges, ME, Moorhouse, MF, and Murr, AC: Nurse's pocket guide: Diagnoses, prioritized interventions and rationales, ed 14. F. A. Davis, Philadelphia, 2016.
- Erickson, E: Childhood and society, ed 2. W. W. Norton, New York, 1963.

- Feldman, D, and Lasher, SA: The end-of-life handbook: A compassionate guide to connecting with and caring for a dying loved one. New Harbinger Publications, Oakland, CA, 2008.
- Foltin, G, Tunik, M, Treiber, M, et al: Pediatric disaster preparedness: A resource for planning, management, and provision of out-of-hospital emergency care. Center for Pediatric Emergency Medicine, New York, 2008.
- Glaser, BG, and Strauss, AL: Time for dying. Aldine, Chicago, 1968.
- Gordon, T: Parent effectiveness training: The proven program for raising responsible children, ed 30. Three Rivers Press, New York, 2000.
- Hausman, KA: Interventions for clients with problems of the central nervous system. In Ignatavicius, DD, and Workman, ML (eds): Medical-surgical nursing: Critical thinking for collaborative care, ed 5. Elsevier Saunders, St. Louis, MO, 2006.
- James, M, and Jongeward, D: Born to win: Transactional analysis with gestalt experiments. Da Capo Lifelong Books, Boston, MA, 1996.
- Krieger, D: Therapeutic touch: Using the hands to help or heal. Simon & Schuster, New York, 1998.
- London, ML: Maternal & child nursing care, ed 2. Pearson Prentice Hall, Upper Saddle River, NJ, 2007.
- Matheny, NM: Fluid and electrolyte balance: Nursing considerations, ed 5 Jones & Bartlett Learning, Sudbury, MA, 2012.
- Martinez, H., and Berry, P: Core curriculum for the hospice and palliative registered nurse, ed 4. Kendall Hunt, Dubuque, IA, 2015.
- Nelson-Marsh, JD: Chronic disorders of neurologic function. In Copstead, LEC, and Banasik, JL (eds): Pathophysiology, ed 3. Elsevier Saunders, St. Louis, MO, 2005.
- Ortner, N: The tapping solution: A revolutionary system for stress-free living. Hay House Inc., New York, 2013.
- Robinson, L: Social work through the life course. In Adams, R, Dominelli, L, and Payne, M (eds): Social work: Themes, issues and critical debates, ed 2. Palgrave-Macmillan, Basingstoke, England, 2002.
- Townsend, MC: Psychiatric mental health nursing: Concepts of care inn evidence-based practice, ed 8. F. A. Davis, Philadelphia, 2015.
- University of Missouri: Handbook of disabilities, substance abuse. Product of RECP7 and curators of the University of Missouri, Columbia, 2006.
- Vallerand, AH, Sanoski, CA, and Deglin, JH: Davis's drug guide for nurses, ed 15. F. A. Davis, Philadelphia, 2017.
